Acid Precipitation: Another critical environmental issue is acid precipitation. It occurs in large regions of the United States and Canada, Europe, and Japan. Attempts to determine the economic impacts of acid precipitation within the United States are highly controversial because of the complex interrelationships and the fact that there

are potential beneficial effects as well as negative effects. Badly needed is solid evidence on how acid precipitation affects crop yields, tree growth, lake ecology, and fish and wildlife habitats.

Weather: Fluctuations in weather are the main cause of year-to-year variations in crop yields. While the weather cannot be altered at the present time, many realistic strategies can be used to reduce the effects of adverse weather on agricultural production, which in turn would reduce the fluctuations in domestic and world food supply and prices. An increasing number of crop growth and resource management models are becoming available, nearly all of which contain weather variables of various kinds such as temperature, rainfall, and solar radiation. The need now is to validate these models in a variety of field situations and make them operational in computerized information systems in many states and research centers. Other ways to reduce the adverse effects of weather include: supplemental irrigation in humid regions, breeding plants that are more tolerant of drought and temperature extremes, and adjusting the growth cycle of plants to avoid likely periods of climatic stress.

Energy

Because energy supplies and costs have stabilized in recent years, the pressure to improve energy-use efficiency and substitute domestically available energy sources for imported fossil fuels has lessened. Since one international incident could seriously disrupt world supplies, prudence suggests renewed effort in research and education. What are the most cost-effective technologies for achieving optimum energy-use efficiency in agricultural production, processing, and marketing? If necessary, energy self-sufficiency in agriculture is attainable. It will require greater use of alternative energy sources like solar, wind, and biomass. Which option is most promising and what incentives would encourage adoption? Research and educational programs need to provide more information on ways to reduce energy needs in all parts of the rural community, including homes, farms, and ranches and in processing, storage, and transportation.

Forestry

The United States is rich in forests and related renewable natural resources. These resources must be managed and used wisely if Americans are to enjoy the full complement of forest-provided values—jobs, wood, wildlife, water, range, and energy—and a varied array of recreation values. Wise management, in turn, requires scientifically sound knowledge and an understanding of human needs—material, aesthetic, and social.

Growth in world demand for forest products is anticipated to increase significantly by the year 2000 and into the next century (Section II). Therefore, the United States has many opportunities to increase exports, particularly in paper products. A wide variety of trade barriers, however, will limit the growth of exports of processed products such as lumber, panels, and paper. Efforts to ease or eliminate some of these barriers are underway.

The most effective way for the United States to satisfy the growth in domestic demand without major increases in price, and to overcome trade barriers in export markets, especially for processed products, is to increase the efficiency of growing, harvesting, processing, and marketing timber. To realize that goal, the following research programs should be emphasized:

- Develop improved silvicultural techniques to increase yields of timber, while simultaneously considering other multiple use demands. This involves the entire range of forest management practices from seed production to harvest and stand establishment.

- Genetic improvement to provide superior tree species for greater yield and increased disease and insect resistance. Forest yield enhancement is strongly dependent on genetic improvement of trees, but the long generation time has hindered progress with current breeding techniques. The new biotechnology tools offer a way to circumvent the long generation cycle of trees.

- Finding ways to reduce timber losses from destructive agents, i.e., fire, insects, and disease. Increasingly, this research is concentrating on preventive measures as well as control methods.

- Development of better utilization technologies to expand the use of currently abundant hardwood species, extend the supply of scarce softwoods, and enable the use of small or low-quality trees now underutilized or wasted.

Economic studies that provide financial guidelines to forest landowners on the economic feasibility of alternative management practices are essential. Domestic and international markets for wood products are changing rapidly and require a continuing analysis of such issues as trade barriers, comparative costs, price trends, supply status, and government policies.

Extension programs in forest land management should concentrate on improving the ability of owners and managers of private nonindustrial forest lands to derive a profitable return from their woodlots. Educational programs would deal with marketing approaches and opportunities, stand regeneration practices, timber stand improvements, and insect and disease control technology.

As the supplies of softwoods in the West become more scarce and expensive (due to declining old growth stocks, increased transportation costs, and high harvest-to-growth ratios) eastern and southern forests will either fill the gap or the United States will continue as a net importer of wood products. This shift in forest production can take place with the help of improved utilization technology. The recent development of press drying allows for the use of short-fiber hardwoods in pulp, making hardwoods more competitive with softwoods. Improved technology in reconstituted panels improves the competitive position of smaller trees, which are in plentiful supply in both the East and South. Many more technologies need to be developed.

Americans look to their forest resources for much more than commercial products. They want a pleasing forest environment in which to hike, camp, hunt, and fish. Forest managers expect the science and education community to identify the nature of conflicts between commercial uses (timber, forage, and mineral production) and noncommercial uses (recreation, aesthetics, soil stability, and water quality) and to identify opportunities that reduce competition among uses.

Range

Range is land that provides or is capable of providing forage for grazing or browsing animals. A complex array of ecosystems, characterized by a variety of vegetative life forms, makes up the Nation's rangeland base. More than two-thirds of the range is dominated by grasslands and shrublands and the balance by coniferous and deciduous forests. Ninety-five percent of the 853 million acres of rangeland are in 17 western states and Alaska. Non-federal owners control almost two-thirds of the rangelands.

Almost 61 percent of the Nation's non-federal rangelands are in poor but improving condition. Much of these lands are arid and semi-arid. They produce less than 50 percent of their forage potential. Rangelands, in addition to producing forage for livestock, provide valuable habitat for wildlife, serve as watersheds, and provide open space and natural beauty that is enjoyed by increasing numbers of recreationists.

Range research has turned from the single-purpose range livestock grazing systems approach to the ecosystem approach; that is, research is based on understanding the interrelationships of multiresource productivity and use. Responding to needs of multiple use management, increased effort has also been devoted to the study of interactions and compatibilities of forage production and livestock grazing with wildlife and fisheries habitats, watersheds, and recreation. Additional research is needed to:

- Expand our fundamental understanding of range ecology for the purpose of improving management practices to sustain productivity for both domesticated and wild animals.
- Increase production through genetic improvement of native range plants. New selections and even new species can be developed that are easier to establish, live longer, and have improved forage quality and water-use efficiency.
- Improve range resource classification, inventory, and monitoring techniques.

The present status of range management and range productivity does not adequately reflect the current state of knowledge. Much can be done to improve range conditions and increase renewable rangeland resource outputs through intensive application of existing knowledge. But effective methods and processes must be developed to transmit technology into application. The extension of knowledge involves not only the delivery but also the presentation or packaging of information for those who would use or deliver it.

Extension programs should concentrate on: the resolution of conflicts from mixed landownerships (private and public) and multiple use demands; and the rapid adoption and application by landowners and managers of new research results that will increase profits and preserve or improve the resource base.

Wildlife Habitat

Wildlife environments will continue to be under pressure from development for living space, mining and industrial development, and agricultural and timber use, as well as energy production. Large scale and continual modifications in wildlife habitats are likely to occur unless wildlife needs are considered. Without these adjustments the opportunities to maintain balanced and stable ecosystems will be reduced. Responding to the public's overall wildlife interests and values will become increasingly difficult under those conditions.

The management of resident wildlife species in the United States has largely been the responsibility of the state fish and wildlife agencies. Habitat management is the stewardship responsibility of the landowner or manager. Land use decisions on much of the privately and corporately owned land are affected by market forces little influenced by wildlife values. Public lands can be used, to some extent, to balance the modifications to habitat that are occurring on private and corporate lands. Knowledge of the habitat requirements of various species, the impacts of alternative land uses, and the means to achieve habitat enhancement effectively will be important considerations in addressing this issue.

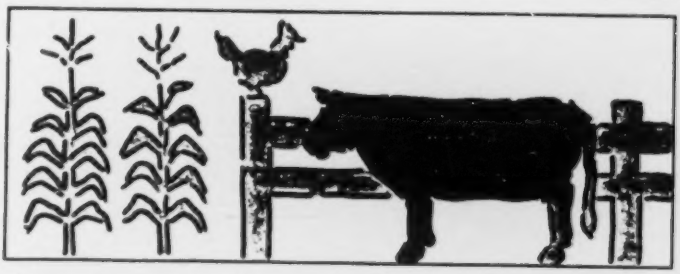
The following kinds of studies should be emphasized:

- Provide an improved base of knowledge on habitat requirements for wildlife species.

- Study the impact of changing agricultural and forest management practices on wildlife species, including threatened and endangered species.

- Find means of habitat enhancement that are ecologically acceptable and cost-effective.

Scientific knowledge and implementation techniques need to be transferred to users as rapidly as possible. Extension program efforts in this area would enable owners and managers to: improve habitat carrying capacity; increase productivity and profitability of income-producing wildlife and fisheries enterprises; increase recreational opportunities; reduce loses from wildlife pests; reduce landowner-user conflicts; enhance the environmental quality of life for both adults and youth in the community; and ensure an improved sense of stewardship to perpetuate a strong natural resources base for future generations of owners and users.



B. Production Agriculture

The production sectors of agriculture are normally categorized under crops and animals. Both are concerned with methods of production and protecting the health and vitality of the organism. Well over half the scientists in agriculture direct their investigations toward improving the performance of crops and animals.

Crops

Probably the largest problem faced by U.S. agriculture is the *high cost of production relative to farm income*. During the period from 1966 to 1979, total farm expenses increased by 320 percent, but cash receipts for farm products increased only 280 percent. Most of the increased expenses are attributable to depreciation and credit as well as equipment, fertilizers, irrigation, and fuel costs.

Agricultural research, education, and extension have brought about major increases in crop productivity. Two examples are corn and soybeans, where the yield per unit of land has increased threefold and twofold, respectively, in the last 40 years. Of this gain, half is attributable to improvements in the genetic characteristics of the plants achieved through plant breeding. For the farmer, this achievement represents a low-cost input. The rest of the gain resulted from better management practices, including enhancement of nutrient supply, improved weed control, and better timeliness of production operations. These are generally high-cost inputs. For vegetable and fruit crops, improvements in these methods have also been accompanied by advances in machine harvesting and in post-harvest storage that makes high-quality products available throughout the year.

Research on crops contributes to these increases in productivity by two primary means. First, the genetic potential for high yield can be improved. Hybrid corn is an example—switching from open-pollinated to hybrid varieties raised the genetic potential of the crop and caused yields to double.

The second approach is to improve yields in unfavorable environments. Examples are increased disease and insect resistance, more efficient nutrient acquisition, and enhanced tolerance of drought, salinity, and temperature extremes.

Potential Crop Yields: Table 4 shows how these approaches affected 12 major crops as of 1975. Record yields are one way of measuring the genetic potential for high productivity; the data show that the record yields of each crop were already very high. However, average yields realized by U.S. farmers were comparatively low. The difference between record yields and average yields was caused by factors that inhibit productivity. Diseases, insects, and weeds contributed substantially to this inhibition. However, the largest losses were due to unfavorable physicochemical environments.

Table 4.
Record Yields, Average Yields, and Yield Losses Due to Disease and Insects, Weeds, and Unfavorable Physicochemical Environments in Selected Major Crops of the United States.[1]

Crop	Record Yield	Average Yield	Average Insect & Disease Losses	Average Weed Losses	Average Losses Due to Unfavorable Environments
		Tonnes/Ha			
Rice	11.0	4.5	2.4	.9	3.2
Corn	19.0	4.6	1.7	.7	12.3
Wheat	14.5	1.9	.6	.3	11.7
Soybeans	7.4	1.6	.4	.4	5.0
Sorghum	20.1	2.8	.7	.5	16.0
Oats	10.6	1.7	.7	.5	7.6
Barley	11.4	2.1	.5	.4	8.4
Potatoes	94.1	28.2	14.5	1.3	50.0
Sugar Beets	121.0	42.6	18.6	5.3	54.4
Processing Tomatoes	152.0	66.4	22.8	22.8	62.8
Fresh Tomatoes	92.4	27.5	13.9	1.8	49.2
Sweet Corn	18.8	10.7	2.1	.8	5.2
Average Percentage of Record Yield	100	34.0	13.3	2.7	50.0

[1]Data on rice from M.D. Faulkner, Rice Exp. Sta., Crowley, LA, 1982; on processing tomatoes from W.L. Sims, University of California-Davis, 1982; on fresh tomatoes and sweet corn from D.N. Maynard, University of Florida, 1982; on other crops listed from J.S. Boyer, USDA/ARS, University of Illinois, 1982.

Crops with fruiting structures of high economic value were more adversely affected by unfavorable environments than those with marketable vegetative structures. This difference is attributable to the complexities of reproductive development, which are often highly sensitive to unfavorable environments. Even in crops with marketable vegetative structures, however, record yields were three times larger than average yields.

These data indicate that opportunities for improvements in plant productivity depend on research and education aimed at improving the performance of plants in unfavorable physicochemical environments and improving overall genetic potential. In addition, because of the substantial losses attributable to diseases, insects, and weeds, research in these areas remains important.

In the future, agricultural science and education must continue its efforts in plant breeding, biological controls for pests, methods of applying nutrients and water, techniques for harvesting and storage, and conservation aimed at minimizing soil erosion and environmental degradation. Research advancements in these areas have been the mainstay of agriculture and can be counted upon to provide a steady improvement year after year. There will be increased need for extension educators to view crop management as an integrated system, with components such as planning, cultural practices, harvesting, and marketing all included in a multi-activity package.

Future Directions: In addition to the traditional technologies, however, it appears that the fields of molecular genetics, plant growth regulation, and the metabolic basis of plant response to unfavorable physicochemical environments will be important for enhancing agricultural production in the future. These approaches have promise because of two recent changes in scientific understanding. First, there has been a revolution in our knowledge of molecular genetics that could not have been predicted as recently as 1969. The opportunity for using this knowledge to improve agricultural technologies is more fully explained in Section IV. Second, there has been an increase in understanding of how plants cope with unfavorable environments.

Basic to the application of these technologies is the need for a wide diversity of genes that can be incorporated into crop germplasm. The continuing loss of wild genotypes and land, together with increasing population pressures worldwide, places particular importance on the need for more activity in plant exploration, mutation, and advanced techniques for recombination. Central to each of these activities is the need for germplasm evaluation and conservation. Such research is long term and of high risk but of inestimable value for plant breeding and for exploring the fundamental behavior of crops.

Scientists have only recently begun to develop molecular knowledge of how plants cope with unfavorable environments. The concepts that predominated as recently as 15 years ago are changing radically. The impact of unfavorable environments is increasingly viewed as having a metabolic basis regulated by plant genes, rather than being inevitably imposed from outside the plant. Rapid changes have occurred in our understanding of how plants cope with freezing, chilling, and overheating, as well as drought. The effect of this increased knowledge is that the impact of unfavorable physicochemical environments is more accessible to genetic manipulation and is brought within reach of the techniques of molecular genetics.

Following are a few areas that hold promise:

Biological Stress—Because diseases often involve microorganisms, for which molecular genetic techniques are best understood, the promise of improvements in disease resistance is considerable.

Plant Regeneration—Tissue culture techniques for plant regeneration offer the promise of large numbers of genetically identical individuals as well as methods for understanding gene expression in plants.

Physicochemical Stresses—Many of the aspects of unfavorable physicochemical environments were previously thought to be imposed inevitably by the external environment. It is now apparent that plants have molecular means for acclimating to these conditions and that much of the plant response is under metabolic control.

Photosynthesis—Single gene products have been identified that could be modified by the techniques of molecular genetics. In particular, both ribulose bisphosphate carboxylase and herbicide-binding proteins have been observed to undergo genetic changes that alter the photosynthetic performance of plants.

Nitrogen Fixation—The molecular basis of nitrogenase synthesis and activity is increasingly understood, and genetic modification of the nitrogen-fixing capacity of both symbiotic and free-living bacteria is being carried out.

Male Sterility—Male sterility is beginning to be understood at the molecular level. This could lead to significant improvement in the efficiency of plant breeding.

Seed Proteins—Most of the proteins stored in the grain of food crops have an amino acid composition that is not optimally balanced for human and animal consumption. The possibility of inserting genetic material that would change the amino acid composition of grain protein is within reach.

Recent Changes in Crop Production: The patterns of U.S. agriculture have changed in the last few years. In 1966, the cash received for crops was 42 percent of the total receipts by farmers. By 1980, this had increased to 50 percent. This shift from animal to plant production is attributable in part to changes in food consumption. The per capita consumption of animal products did not increase between 1966 and 1980; consumption of plant products, however, increased an average of 14 percent. Some of the increase was attributable to consumption of grain and some to greater use of vegetables, melons, and fruits. Of even greater significance is the change in U.S. crop exports. In 1966, 23 percent of the total grain production was exported. By 1980 this share had risen to 36 percent.

Accompanying these production changes has been a continuing trend toward larger farms. The raising of grain crops lends itself to large-scale production methods. These units take advantage of corporate structuring of assets, computer forecasting, and advanced accounting methods. They are increasingly capitalized and make extensive use of credit. Specialty crops, while grown on smaller acreages, are also tending toward increased farm size.

In this situation, agricultural forecasting is gaining in popularity. Computers are now within reach of most operators, who are better able to anticipate pest and weather problems, income and cost relationships, and the scheduling of farm inputs.

As grain production becomes more prevalent, added research and extension will be needed to protect crops against pests that are more devastating as the cropping system becomes more dependent on monoculture and a narrower genetic base.

At the same time, research needs to emphasize ways to increase production and quality of small-acreage, high-value crops directly consumed by the population. Because of the high economic returns from these crops, advanced methods of irrigation and nutrient supply are possible, as is hormonal control of flowering and fruit sets. Many of these crops are perennial, so research requires large financial resources and years of effort. Basic knowledge of mechanisms of fruit set, propagation, and time to reproduce are often lacking. This can be a problem for farmers and commodity groups having limited resources. Consequently, there is a need for expanded, long-range genetic and cultural research to support these diverse crops.

With increasing reliance on large-scale operations, optimization and yield forecasting are becoming important features of agriculture. Since computers are within reach of individual farmers, modeling concepts can provide important means for increasing the efficiency of resource use in crop production. Science and education must provide more information and computer programs that can forecast for specific crop systems the benefit of various inputs in terms of yield, income, capital requirements, tax consequences, etc. There is a tremendous need for improving the usefulness of these tools.

Animals

Animals provide humans with food, fiber, work, fuel, fertilizer, recreation, and a vast array of cosmetic and medicinal products. Of all animal products utilized by humans, milk and meat rate first. Nonfood products include wool, hair, hides, and pelts. In the developing world, animals provide the majority of power for agricultural enterprises. Animal wastes contain millions of tons of nitrogen, phosphorus, and potassium to fertilize crops.

Even more so than for crops, animal agriculture is facing a severe cost/price squeeze. Buying patterns are shifting (e.g., increased consumption of poultry and fish) and production costs are rising faster than the market is willing to absorb them. It is important for society to address these issues, because the nutritional needs of the U.S. population are still met, to a large extent, by foods of animal origin. Science and education programs can help animal agriculture adjust to shifts in consumer buying habits and provide technologies that improve productivity.

Opportunities for Improving Productivity:[4] Today we have the same number of animal breeding units in the United States as we did in 1920, yet animal food production has increased 2.25 times. This trend can continue and even accelerate through the year 2000 to meet the increased demands projected in section II at an affordable price to the consumer. The increased production per animal can be achieved largely through improvements in three major areas: 1) forage production and utilization; 2) reproduction and genetics; and 3) physiology and nutrition.

Forage Production and Utilization: Approximately half the total U.S. land area involves grazing lands (pastures and rangelands), which produce forage as a renewable natural resource. Utilization of that forage resource provides many complementary benefits for the well-being of the American people through food and fiber production and enhancing the quality of the Nation's environment. Ruminant livestock are capable of consuming the vast forage resources that cannot be utilized directly by humans. Ruminants can provide a unique buffer for fluctuating grain supplies caused by crop surpluses or failures, and thus may be considered a strategic reserve human food supply.

Plant breeders and agronomists are improving varieties of forage plants and extending their adaptability. Extension specialists are transferring information about known technologies such as overseeding grasslands with legumes, establishing grass-legume mixtures, and improving grasses with nitrogen fertilizers.

[4]This material was taken primarily from a paper written by William Hanzel, Cornell University, for a RCA Symposium held December 5-9, 1982.

57-279 O - 87 - 30

Large losses in protein contents and digestibility occur in most forage plants as they mature. It may be possible to delay the maturity of forage plants in order to preserve their protein contents and digestibility. Significant advances in this area will likely occur before the year 2000.

Reproduction and Genetics: Current and emerging developments suggest that a new system of animal breeding could be in use by the year 2000.

Estrous cycle regulation techniques will likely be perfected so that large groups of cattle, sheep, swine, and goats will be fertile to insemination at one pre-set time. Nonsurgical embryo transfer techniques will be perfected, making possible the dissemination of embryos produced by outstanding sires and dams. Superovulation techniques will be perfected so that large numbers (100 or more) of fertilizable eggs can be harvested at one time. *In vitro* (outside the living body) fertilization and embryo freezing techniques will be perfected, so that embryos can be stored in the laboratory for indefinite periods. It will become possible to control the sex of the embryos, and fertility of the recipient animals will be greatly improved. Thus, our artificial inseminators may become "artificial embryonators", who will perform a service consisting of placing genetically superior embryos into the uteri of animals. These embryos will be conceived in the laboratory and stored frozen until needed.

Physiology and Nutrition: Increased production of meat and milk per animal, as well as improved carcass characteristics, will also be achieved through improved methods of regulating the animal's endocrine system and metabolism. Within 20 to 30 years the major pituitary and hypothalamic hormones will have been synthesized in relatively large quantities by recombinant DNA techniques, and new ways to administer them to animals will have been developed. Bovine growth hormone has already been produced in this way and shown to increase milk production in dairy cattle by about 10 percent, without increased feed intake. New and more effective drugs, especially of the "rumen additive" type, will be developed to enhance feed efficiencies. Increased use will be made of byproducts and waste product feeds.

The years between 2000 and 2030 will likely be characterized by the application of genetic engineering techniques to all classes of livestock and to the forage plants they consume. It is extremely difficult to predict the nature of the changes that may occur. Theoretically, it is possible to modify the production of hormones and enzymes in a predictable way by introducing new genetic material into the embryo. The resulting changes in production traits are not known, however, because most are affected by numerous genes.

Animal Protection Issues: Throughout the world, disease, internal parasites, and toxicants cause major losses and are important causes of low animal productivity. In the United States, they cost livestock producers, and subsequently consumers, an estimated 20 percent of the farm income from livestock and poultry products.

• New and improved methods are needed for identifying losses from diseases, parasites, and toxicants. Tests are needed for diagnosis of recognized diseases, detection of inapparent carriers, identification of new diseases or sources of loss, and assessment of losses attributable to individual diseases.

• The associations between environmental stress, nutrition, and animal health are largely unknown. Factors that influence infection by disease, including the effects of hormones on the immune system and the response of animals to vaccination, should be studied.

• Recombinant DNA technology is expected to revolutionize the production of vaccines and other biological materials that are needed to prevent disease or promote growth. Advantages of the technology are safety of the products and the ease with which abundant supplies of vaccines and materials can be produced.

In the United States, insects, ticks, and mites that affect livestock and poultry cause annual losses estimated at more than $3 billion. Insects, ticks, and mites also directly affect people by impairing th health and productivity through annoyance, debilitation, and disease transmission.

• A balanced program of basic and applied research should provide the knowledge and technologies that are needed to alleviate those losses. Methods of detecting infestations of insects, ticks, and mites need improvement, and thresholds of economic importance must be determined for species that affect man and animals.

• New and improved methods of reducing losses should be emphasized in research on the chemical control of insects, ticks, and mites that affect man and animals. Genetic methods of altering the pests should also be devised.

• Applied research will be used to combine chemical control, biological control, and other control approaches into integrated systems for the management of insect, tick, and mite populations so they can be maintained below thresholds of economic importance.

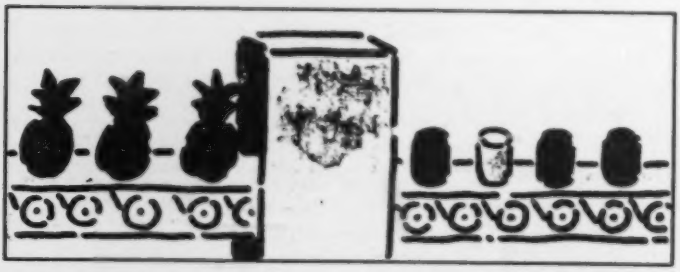
Extension programs in animal production and protection will concentrate on the use of more integrated approaches to solve problems and improve profitability of livestock operations. Multidisciplinary teams from extension, industry, and research will cooperate in problem identification and solutions. Modern communication systems will serve as a key vehicle for program delivery. Reproductive efficiency and improved stewardship and utilization of grazing lands will receive high-priority emphasis.

Food Safety, Environment, and Related Issues: In the 21st century, the consumer will expect animal food products to be even more safe and nutritious than at present. Producers and regulators need procedures for defining and certifying the wholesome-

ness of animal products (wholesomeness is generally defined as clean, free of disease, residues, chemicals, or other contaminants of any kind). This requires monitoring production systems for residues and analyzing the causes and sources of residues appearing in the final product. Additionally, science and education should develop and transfer to producers and processors cost-efficient alternatives to practices identified as causing residues.

If animal agriculture is to be publicly acceptable, producers must adopt more effective methods to prevent the pollution and environmental degradation associated with current animal production systems. To develop these methods, the current level and major sources of adverse environmental impact associated with animal agriculture need to be identified and evaluated. New, economically viable systems for utilizing animal production waste and other byproducts need to be developed. Potential uses may include single cell protein conversion of waste for feed or conversion of waste to feed, energy, animal bedding, or other useful products. Cost-effective ways need to be found to control or eliminate the presence of odors, flies, rodents, litter, and other undesirable pollutants.

An emerging issue also requiring careful attention from a public education perspective is the application of new biotechnology methods to animal agriculture and animal research. Public sensitivities are high when prospects of changing the form of living organisms are discussed, yet animal agriculture will likely adopt some of these scientific developments and producers will not want to forgo the potential improvements in productivity.



C. Processing, Marketing, and Distribution

The importance of processing, marketing, and distribution is evidenced by the fact that two-thirds of the retail cost of food is associated with this segment. It is expected that roughly three-fourths of the retail value of food, fiber, and forestry products will be represented by these activities by the beginning of the 21st century. The beyond-the-farm-gate sector of the U.S. economy will become increasingly critical to national employment, the inflation rate, and the balance of payments.

As we look to the year 2000 and beyond there are three major areas of concern: 1) increasing transportation costs; 2) processing and packaging efficiencies; and 3) storage and handling issues.

Increasing Transportation Costs

The problem of increasing transportation costs is caused by several factors, including the increasing cost of energy, regional adjustments in agricultural production, and the shifting centers of population. Intermodal transportation systems are needed which utilize the most efficient aspects of motor vehicles, trains, airplanes, and ocean vessels. While the motor truck has been a dominant factor in agricultural transportation in the second half of the 20th century, the energy efficiency of rail services for intermediate and long hauls will make rail transportation increasingly important in the 21st century.

The higher cost of transportation may force the relocation of agricultural production for high-value perishable agricultural commodities closer to population centers. As a result, innovative production systems may need to be explored and evaluated. A few examples of these systems include hydroponics, solar energy greenhouses, and waste heat utilization.

A transportation system must be developed to move raw agricultural commodities and finished products to consumers more efficiently. This requires an integrated research and development program with participation of government, private, and university sectors. An initial requirement is the need to open up communication among these three groups to ascertain the barriers to productivity growth and efficient resource use. A specific example is standardization and unitization of containers used in the food industry. Can uniform standards be developed to permit palletization and unit handling of all types of food products, serving all types of transport carriers? What is the economic impact of current and alternative government regulations affecting the transportation system?

Processing and Packaging Efficiencies

Costs associated with converting raw agricultural commodities into finished products are expected to increase. These increased costs will influence processing and packaging efficiencies. Problems with productivity growth efficiency are expected, particularly from energy inputs, labor, raw materials for packaging, and capital. The need for a low-cost, year-round, varied food supply will require continued improvement in this segment of the food and agricultural system. New methods of food preservation which use fewer purchased energy inputs are needed, as are technologies which lower labor costs, possibly via robots.

For most industries that process and distribute farm products, the rate of labor productivity growth (output per employee hour) has declined since 1972. While labor productivity improvement is an obvious place to start, virtually no research is looking at improving total factor marketing productivity of either firms or marketing systems.

Low productivity in this sector costs the United States jobs, as labor-intensive production and processing are shifted to other nations. Research on improving productivity should emphasize: 1) improving distribution of food and fiber; 2) maintaining and measuring product quality, with concurrent reduction in losses and longer storage life; and 3) developing new opportunities for agricultural products. Productivity can be gained in the restructuring of container sizes (i.e., modular containers) to make more efficient, unitized loads. This would improve handling and storage efficiency, but much research is still needed to document the costs, benefits, and potential beneficiaries.

New technologies in processing and packaging will be necessary to make possible the continued availability of a low-cost, year-round food supply. This research must be coordinated with agricultural production research and development. Traditional plant and animal breeding programs, plus new efforts in genetic engineering, must be coordinated with processors and retailers.

The environmental issues related to processing and packaging will continue into the 21st century as shifts occur in the food and agricultural system. The increasing expenses associated with the disposal of agricultural byproducts and wastes from processing operations will make their utilization more attractive. This will allow more efficient use of agricultural commodities, while at the same time minimizing the adverse effects on the environment.

Storage and Handling

Most agricultural commodities experience numerous handlings and pass through short- or long-term storage facilities as they move from the farm to the consumer. These handlings and facilities contribute to excessive food costs and losses. Although post-harvest losses of agricultural commodities have not been adequately evaluated, it has been estimated that research on reducing food losses due to pests alone could save $1.5 billion annually in the United States. Research on reducing the storage and transportation losses of fruits and vegetables could increase the supply of these products from 15 to 30 percent.

Most losses occur because control procedures are considered too costly. Unfortunately, deeply entrenched operating procedures tend to accept certain post-harvest losses as normal consequences of dealing with a commodity. Relatively small losses of cereal grains here and there throughout post-harvest handling and processing attract little attention, even though the total loss may be highly significant. Effective and economical technologies must be developed for improving storage and handling.

Storage technology must be upgraded to meet the challenge of storing new varieties of commodities and controlling insects and bacteria that have become increasingly resistant to current control methods. Research is needed to determine storage, drying, and processing conditions (temperature, humidity, etc.) that will minimize the growth of bacteria and molds. For commodities such as horticultural crops, this reduces incidence of rot and, therefore, the occurrence of mold toxins and loss of nutrients.

Research can find ways to ensure good arrival condition for products that are not presently exported. The quality of cereal and oilseed products can be increased and losses can be minimized if transportation, storage, and handling procedures are improved. Research is needed on product mechanisms that change under storage and handling conditions; for example, the effects of chemical residues on the nutrients and keeping quality of peanuts and peanut products for the export market.

Reduction of losses presumes the ability to identify the causes and magnitude of the loss, assess the likelihood of preventing it, and assign cost/benefits to alternatives in order to decide whether to adopt them. Unfortunately, this is not the case. The movement of new varieties and improved qualities of agricultural products through conventional and, in some cases, outmoded storage facilities with poor handling methods creates the risk of increased losses and an inability to maintain a competitive position with other nations.

Extension programs beyond the farm gate are directed primarily at processor and distributor audiences. Many of these firms lack the resources to be aware of recent innovative techniques and management practices that can improve operating efficiencies and enhance product quality.

D. Agricultural Policy—Including Adjustment Concerns

Public policy involves the creation and management of institutional arrangements that affect the behavior of farmers; those involved in supplying inputs and marketing food products; and consumers. Appropriate policy choices can remedy market shortcomings that would otherwise harm the economic well-being of consumers, farmers, and rural society.

Intelligent policymaking requires a knowledge base for the agricultural economy that is not only descriptive and historically accurate, but also useful for predicting the consequences of policy alternatives. While social scientists have made substantial progress in understanding the functioning of commodity and input markets, we are far from the level of understanding necessary to meet present and future challenges in policymaking. We need to develop a better understanding of how farmers, consumers, and others respond to market and policy institutions; to anticipate the individual and aggregate implications of various policy actions; to identify and provide for the information needs of those involved in the U.S. agricultural economy; and to prepare those who will operate within the agricultural system to do so with full knowledge of market and policy institutions.

Policy issues expected to be important in the U.S. agricultural economy in the year 2000 and beyond have been identified in the following areas: (1) the position of U.S. agriculture in the world economy; (2) effects of recent developments on size, cost, and asset distribution of farms; and (3) the role of the federal government in the agricultural economy.

Position of U.S. Agriculture in the World Economy

As shown in Section II, world commodity markets are crucial in determining the economic health of U.S. agriculture. In recent testimony before the U.S. Congress, Secretary of Agriculture John Block identified six causes of recent farm economic problems. All six—high worldwide production, past U.S. export embargoes, global recession, the strong dollar, agricultural protection policies in foreign countries, and financial difficulties of our foreign customers—involve the world economy. Yet, the economic role of only one of them, high production, is well enough understood to have clear policy implications.

For the others, we either do not have a full explanation of their importance, or, if we have a well-developed theory (as in the role of the strong dollar) we do not have sufficient practical knowledge.

Research is needed on the economic and other factors that motivate farmers, consumers, and governments in the United States and elsewhere around the world. A much better understanding of who the world agricultural economy operates and how individual farmers and consumers behave within it is required. Just how differently do farmers, consumers, and taxpayers behave in the United States, the European Community, Brazil, Argentina, Australia, Canada, and other countries? Why is the United States a "residual supplier and adjustor"? If the U.S. were to attempt to change its role in world markets, how would major competitors and customers react?

In many instances, scientific investigation will involve a fundamental investment in improved information based on events abroad that influence world trade. How are prices determined? To what economic signals (e.g., market price and government price support) do U.S. and foreign farmers respond in making production and marketing decisions? Just how responsive are they? If foreign producers respond to U.S. farm program supports, how does this interaction occur? What does it imply for U.S. policymaking?

Over the past decade, U.S. agriculture has moved from a closed to an open economy. Exports now play a crucial role in the economic health of the U.S. farm sector. Research into the nature of world markets, as already noted, is basic to the performance of U.S. agriculture in the years ahead and to the setting of U.S. agricultural and trade policy.

Extension programming must be broadened to not only make farmers and others more aware of international markets but also to increase their knowledge of the workings of these markets; i.e., the economics, politics, and other dimensions.

Adjustment Needs Relating to Size, Cost, and Asset Distribution of Farms

Agriculture in the United States is evolving from a way of life into a large-scale business. In 1981, agricultural production units were made up of 112,000 large farms, which produced 49 percent of the U.S. farm output; 582,000 medium-size farms, which produced 38 percent of the output; and 1,742,000 small farms, which produced 13 percent of the output (Council for Agricultural Science and Technology, 1983). What are the long-term implications of this trend, e.g., ownership patterns, economic vitality of agricultural and rural communities, as well as the cost of food to consumers? At issue too is the role of technology in this development, e.g., what technology best serves the adjustment needs of small, medium, and large size farms?

The link between farming and the subsequent stages of the food system is complex and growing more so. There are fewer buyers and larger buying firms. This increased concentration has led to many changes, including the greater use of contractual arrangements and pre-arranged pricing procedures, suggesting that some producers will experience greater difficulty in obtaining inputs and entering some markets.

These and other changes over the last two decades are expected to continue. The food system will continue its shift from a commodity-production orientation to a consumer-product-merchandising orientation. The agricultural production sector, once the direct supplier of many consumer food products, is now the source of raw materials for a food system dominated by processing, distribution, and marketing. And the agricultural sector increasingly will focus on international markets. All of these trends suggest that agriculture will become more dependent on national policies and world development—activities that introduce price instability for commodities as well as inputs. The agricultural sector has demonstrated the capacity to respond, but certain classes of farmers and portions of the agribusiness sector find adjustments to these conditions difficult. The small- to medium-size full-time farm is especially vulnerable. These farmers often are heavily indebted and experience cash flow problems.

As the participants in the agricultural sector adjust to change, public intervention is needed at times to facilitate these adjustments to help maintain a stable and viable agricultural industry. This assistance is achieved through direct governmental policies and programs such as price support and credit programs, but also through production and marketing research designed to help those in economic difficulty.

Extension plays an important role in educating producers, consumers, and others about the farm sector—its cost and return structure, and implications for financial viability under various economic and policy settings.

Role of the Federal Government in the Agricultural Economy

Periodic excess supplies of agricultural products have created economic and political crises over the past 50 years, and will almost surely continue to do so in the future. As the United States assumes a more active involvement in world markets, the uncertainty that weather and international economic events bring to the demand for food products will give rise to an uncertain operating environment for farmers, marketers, input suppliers, and consumers. Policies will, no doubt, be advanced in response to the periodic occurrences of surplus and high demand. Research is needed to develop longer-term anticipatory policies that meet society's interests in stability for the agricultural economy. This will require the extension and adaptation of economic theory, the development of necessary data bases, and further evolution in our formal analytical capabilities.

Farm organizations, public interest groups, the executive branch, and the Congress need objective economic input into decisions. For the democratic process to work, policy alternatives and their consequences need to be frankly and openly discussed. An improved forum of interaction between policy analysts, policymakers, and the public is needed. The processes—and incorporated values—by which the results of policy analysis are input into policy decisions need attention with a view toward openness, clarity, and general understanding.

E. Families and Communities

Families in rural and urban communities have a major impact on agriculture through their consumption and nonmarket production practices, their provision of human capital, and their concern about the quality of the environment. The agriculture sector, in turn, influences family and community well-being. Food is a large item in the budgets of consumers, the largest item for some, and is purchased more often than any other. Consumers continue to express concerns about nutritional values, additives, chemical residues, honesty of grades and standards, and price. Economic well-being of farm families has an indirect influence on communities, especially those whose resource base is heavily dependent on agriculture. Economic well-being of all families is a significant factor affecting the overall economic status of the country. The

legitimacy of the issues raised by environmentalists will continue to be debated, but the consciousness that this movement has raised among non-farm residents is not likely to disappear.

Human Nutrition

The well-being of an individual or a nation depends upon people having nutritionally adequate food. Problems arise when there is an imbalance between the food consumed and nutritional needs. There is increasing awareness of the relationship between health and food. The role of nutrition in maintaining health—or the role of faulty nutrition in causing or contributing to disease—is of greater concern as people live longer and seek to remain free of diseases associated with aging. In addition, there is a growing interest in possible relationships between food and mental well-being.

Nutrient Composition and Human Nutrition Needs: Change in the nutrient composition of the food supply is accelerating. There are changes in plant varieties, animal carcasses and processing—all potentially altering the nutritional value of food. We need to improve our capability for measuring nutrients in food. These methods must be reliable and suitable to a variety of applications. Knowing the amount of nutrients in food is not the whole story. We must also measure the extent to which nutrients present in food can actually be absorbed. Current animal and human experimental methods need improvement.

To improve the output of workers it is important to understand the relationship of what people eat to their mental and physical performance. Additional research is needed to identify changes in mental and physical functions at different ages and under conditions of marginal malnutrition. Biochemical and clinical indices need to be developed that correlate well with performance measures. Fundamental studies are needed to identify the mechanisms the body uses to control energy intake.

Current ability to obtain accurate information about what people eat is greatly limited. Such information is required for reasonable planning and for education purposes. Information can be obtained about the total amount of food "disappearing" in the Nation, but there is little or no information about how much is eaten by people, how much by domestic animals, and more importantly, how much is lost in various steps of processing and distribution and in household waste.

More emphasis needs to be placed on providing the general population with credible information about nutritional requirements. This information should emphasize the wise use of foods for enjoyment and for maintenance of life-long health.

Extension programs in foods and nutrition need to concentrate on the safety, wholesomeness, and health implications in the shipment, handling, storage, preparation, preservation, economics, and utilization (waste elimination) of food by the retailer,

consumer, and home producer. These programs should provide the individuals and families the knowledge base with which to make informed decisions for optimum safety, nutrition, and health. The information sources need to be based on research, then tailored for optimum understanding and usefulness according to the age, ethnic, education, and economic characteristics of the audience.

Role of Nutrition in Aging and Health Maintenance: Fundamental improvement in the health of an aging population requires a better understanding of how food affects both the maintenance of physical and mental performance during aging and susceptibility to diseases such as heart disease, hypertension, and cancer. Fundamental research on the role of nutrition in altering the rate at which people age, including the rate at which lean body tissues are lost, should be increased. This will involve studies with cell cultures and animal models in addition to long-time studies in human populations.

The most appropriate vehicles for educating the public on the usefulness of aging research should be investigated and then developed. People need to know how to meet nutritional needs with limited financial resources and limited mobility and how nutrition can affect the diseases commonly associated with aging. As new information is uncovered, it should be transmitted in a clear, concise form to all relevant parties.

Youth, Family, and Community Development

Science and education must deal with the challenges that youth, families, and communities will face in meeting the demands for the future production of food, fiber, and forest products. Efficient production no longer depends only on scientific discovery or technological application. The era of simplistic, unencumbered decision-making—public or private, individual or group—is past. The productive capacities of people, the economic and social structure of communities, and the effects on the environment of production and consumption activities all must be taken into account.

Rural Economic and Human Resource Base: Rural areas survive according to the strength and viability of their economic base and they reflect this in their essential character. From 1940 to the late 1960's, rural population declined significantly because of farm mechanization and consolidation. Beginning in the 1970's a reversal occurred and by 1980 approximately 3.5 to 4 million more people had moved into nonmetropolitan areas than had moved out. In the 1970's non-farm sources of rural employment increased at above-average rates, e.g., in mining, service businesses, wholesale trade, communications, public utilities, finance, insurance, and real estate. In addition, there has been significant growth in transfer payments such as retirement, social security, and government support programs.

This alteration in the rural economic base over a 40-year period has had significant impact on production agriculture and on resource use. In addition to the increase in off-farm employment of farmers and their families, many rural residents do not now have a direct interest in farming. They are concerned more about the appearance of the rural landscape; building homes, businesses, and roads; and recreation opportunities.

Studies need to be conducted on how farmers and other rural residents can most efficiently share land, labor, and capital resources. Local governmental units, such as county councils and development boards, make decisions on land use zoning, taxation, water developments, and waste disposal that affect all rural residents, including farmers. These local units of government and other interested parties need much better information for making decisions than they now have. Improved knowledge can help decisionmakers reduce conflicts and create a better environment for farmers and their non-farm neighbors.

People in rural and urban areas need more job training, better information systems, and more flexible ways to upgrade skills. More importantly, people—especially youth—need reinforcement and human support systems that will encourage less antisocial behavior and more productive pursuits. The need for upgrading human resources will challenge all our institutions to: 1) provide improved information on market trends and opportunities for both youth and adults; 2) provide training opportunities that will help keep skills current and productive; and 3) encourage public and private-sector investments necessary to keep human resources productive. Rural areas present particular challenges in serving the poor, elderly, and youth due to limited transportation options and the effects of low population density. To encourage these developments, researchers and extension specialists need to work with communities and to identify consequences of leaving human development to chance.

Environmental Issues: Criteria for selecting agricultural production and processing practices and assessing new technological developments are being broadened. We have come to realize that what promises to be best for the producer in the short run may not necessarily be best in the longer run for either the producer or society. In addition to finding more efficient use of production inputs we recognize that there is a need to incorporate environmental protection goals into our technologies. How can fertilizers, herbicides, and pesticides be limited to their intended use and not cause off-site damage? How can animal production units be better integrated with other uses of the rural environment?

On the other side of the coin, the rural and urban population centers need to find better ways to dispose of their waste materials. Much of these wastes are improperly dumped in rural areas now, causing controversy and conflict. Improved waste management can occur using known reclamation techniques and through the active pursuit of new practices such as converting wastes into useful economic products. In-

creased understanding of local environmental issues by producers and consumers can help to obtain a more desirable balance between technological development and preservation of the natural environment.

Family and Consumer Programs

The economic well-being of both rural and urban families depends on their level of purchasing power, income stability and resource management skills. Programs in the consumer area cover the interactions people have with the marketplace as income earners and as purchasers of goods and services, and the production, consumption, and management activities at home that affect how well families use their resources. Improvements in the well-being of consumers that result from these programs are returned as enhanced human resources that will increase productivity of farms and other sectors of the economy.

Current national trends will influence the direction of programs focused on the consumer and families.

- The first is the complex and uncertain environment in which families must make economic decisions and manage income. For farm families, net farm income and farm debt levels have been a concern for the last several years; for all families, the relative stability of prices and sustained growth in real incomes of the 1950's and 1960's gave way to inflation and unemployment in the 1970's and early 1980's. When economic conditions are relatively stable, plans are often based on the assumption that the future will be much like the present. That assumption is no longer valid.

- Second, to expand their level of real income and provide greater income stability, many families have become two-earner families. In 1981, 51 percent of all wives were in the labor force, compared with 41 percent in 1970. While some wives work for personal satisfaction, the majority enter the labor force out of economic necessity. Among farm families, for example, over half of the farm women who work off the farm report that they do so to provide money for their households and farms.

- Third, the living arrangements of the population have changed to include more single-parent families, particularly women, who are likely to have incomes considerably below the median and who are likely to have less time to manage their resources. In addition, the population includes more elderly persons living alone.

- Finally, the lengthening of the life-span and the resultant increase of older Americans in the population will continue. This demographic change is the result of increased life expectancy and declining birth rates. By 2050, it is estimated that the population of persons age 65 and over will make up more than 20 percent of the population, compared with 11 percent today.

Data Base Needs: Improved coordination of existing national, regional, and local data bases would make them more useful in research and education programs. Researchers and educators need to find ways to predict the consequences of management practices and decisions. To determine what leads to family economic stability and progress, reliable measures of economic well-being need to be developed and tested. Comprehensive data are needed on current resource management practices, marketplace activities, and financial resources of elderly individuals and households. In addition, retrospective data are needed on major financial decisions, major changes in family status, financial resources, and ability to function at home or in the marketplace.

Education Resource Needs: Although the late 1980's may offer a break from economic uncertainty, families will face a much more complex environment. Financial and other consumer services will be deregulated. Technological advances will change both the way consumers receive information and the way they are billed for services. These factors will expand consumer choices and increase their decision-making responsibilities. Changes in federal and state laws presage growing reliance on individual responsibility and decreased institutional involvement in family financial affairs.

The general aging of the U.S. population suggests that in the future, with proportionally fewer workers and more retirees, a smaller portion of retirement income will be provided through government and social programs, such as Social Security. Retirement planning may need to refocus on independent sources of income such as savings, investment earnings, and part-time or intermittent employment. The desire of older persons to maintain their own homes and the increasing geographic separation of families may make it difficult for the very old and others with physical limitations to obtain needed goods from the marketplace, maintain a safe and comfortable physical environment, or otherwise provide for their own basic needs.

As families seek to improve their security through expertise in management and decisionmaking, electronic technology will provide needed outreach potential. Extension efforts must focus on using all media in new ways, using computers to process the increased amount of information needed to make decisions, and helping consumers select and use appropriate computer hardware and software for farm and home needs.

F. International Activities

The United States has a long and enviable record of sharing its resources and knowledge with other countries in the continuing effort to promote economic stability, reduce poverty, and solve world food problems. President Reagan, in a letter to Congress on July 11, 1983, noted recent important developments in international science relationships and stated that they reflect "...one of our principal foreign policy goals—to give science and technology a more prominent position in our relations with other countries." The President noted that "...international collaboration can

help advance many of our own national interests," and expressed his commitment "...to using the advances in science to overcome both national and international challenges."

While international programs in the agricultural sciences make up an extremely complex system, U.S. agriculture has the basic ingredients to insure that its role is one of leadership. They include: 1) a strong and viable U.S. agricultural science system, 2) a solid and proven university-USDA relationship, 3) an effective partnership with the private sector, 4) policies which articulate and give emphasis to scientific cooperation, and 5) experience in a wide range of international cooperative activities. Future plans and policies can build on the present agricultural science system.

Advantages of Technical Exchanges

Scientific and technical exchanges with other countries make it possible to obtain and share agricultural data, collect exotic germplasm and biological materials, and share information that can improve the efficiency of forestry, crop, and livestock production.

Some developed countries are more advanced than the United States in knowledge and state-of-the-art technology in selected scientific areas. Western European countries and Japan are on the leading edge of knowledge in biotechnology. Japan, for example, is the world leader in continuous fermentation technology. Other countries are more advanced in areas such as dry-land productivity, water-use efficiency, use of controlled atmosphere environments, tissue culture, irradiation sterilization of foods, and control of certain animal diseases.

A concerted effort is needed to promote scientific cooperation with these countries. The number of agricultural scientists in Japan, Western Europe, and the U.S.S.R. has increased more rapidly than in the United States over the past 25 years. Much of Japan's economic success has been driven by government investment in development and emphasis given to the educational system. Our collaborative efforts are limited and need strengthening.

Training

USDA and land-grant universities cooperate to train agriculturists from developing countries and to strengthen the capabilities of USDA and U.S. colleges and universities in areas of importance to international research and development. These programs have made it possible to train thousands of foreign students in the United States and many short course participants in foreign countries. The expertise required by USDA agencies and U.S. universities over time covers nearly the entire spectrum of disciplines. Thus, the short supply of expertise in the U.S. agricultural sciences also affects the international program efforts of U.S. agencies and universities. Additionally, U.S. scientists and educators need more experience and training in international programs and policies such as small farming systems, small-scale marketing systems, new crops, agricultural research administration, and integrated research and extension applications under field conditions.

IV. Needs of Science and Education System to Continue Solving Problems of U.S. Agriculture

The material in Section III shows how science and education programs can help U.S. agriculture meet changing demands. To continue that assignment, the science and education system must train future scientists and managers, maintain and improve its knowledge base, and integrate new equipment and tools into its daily operations. In other words, the science and education system needs to continually revitalize itself. It is important to remember that tomorrow's gain in scientific agriculture has its foundation in the healthiness and vitality of today's science and education community.

The following topics are addressed—scientific expertise needs, biotechnology developments, information systems and computers, maintaining a scientific base, and equipment and facilities.

A. Developing Scientific Expertise in Agriculture

This Nation's agricultural system is increasingly dependent on high technology. To maintain and improve productivity levels, manage the resource base, provide high-quality products, and protect the environment requires a constant supply of food and agricultural scientific expertise. Currently, there are severe shortages of trained faculty to teach and conduct research in such areas as biotechnology, food sciences, human nutrition, animal health and reproduction, soil and water sciences, international marketing, and agricultural engineering.

Faculty Development and Inducement Needs

Many agricultural scientists and faculty received their formal education 20 to 30 years ago. These scientists most likely require additional training in order to operate in today's scientific environment. Other factors contributing to the decline of agricultural scientific expertise at universities are inadequate faculty salaries and limited promotion opportunities. These factors make it very difficult for universities to retain highly qualified agricultural scientists. Some faculty members have left for positions in industry, where salaries and state-of-the-art research facilities are more attractive. Others have gone to better financed schools of science. This drain of agricultural scientific talent from universities and the public sector to agricultural industries threatens the resolution of high-priority problems of agriculture. The private sector is not likely to address problems or conduct activities primarily in the interest of the

public good: basic and disciplinary research, training managers and scientists, or addressing environmental and natural resource issues.

Unless something is done, it is probable that the brain drain from agricultural colleges during the next 10 years will be similar to that from engineering colleges during the past 5 to 10 years. Faculty development (including retraining) and inducement strategies must be augmented. Fringe benefits and incentives for qualified scientists to remain in faculty positions must be created and well articulated. These might include: a) more consulting for pay; b) salary supplements; c) named professorships; d) changed patent policies; e) contractual agreements; f) partnership agreements; g) improved space and equipment; and h) part-time appointments (Division of Agriculture Committee on Biotechnology, NASULGC, 1982).

Graduate and Undergraduate Programs

Graduate student programs in the high-tech fields are not attracting sufficient numbers of students to meet the need. At universities, research is inextricably linked with graduate education programs. The primary source of support is research formula funds, grants, and contracts.

Another facet of this issue is the decreasing enrollments of undergraduate students in agricultural sciences. Agriculture, like other scientific and technical disciplines, must compete for the limited number of students who acquire sound scientific preparation in the secondary schools. Colleges of agriculture must dramatically modify curricula emphases and instructional programming and management in a number of scientific disciplines. For example, a recent survey showed only two land-grant universities among the 10 top-ranked schools offering graduate programs in cellular and molecular biology (University of Wisconsin—fifth; University of California at Davis—eighth). Student development efforts must increasingly focus upon the professional nature of food and agricultural careers. Traditional images need to be modified so that prospective students will more objectively evaluate career opportunities in agriculture along with other professional disciplines like medicine, law, and engineering. In addition, current degree programs must change to accommodate the expansion of interdisciplinary courses and curricula that encourage the use of electronic communications to enhance interstate and interregional research and teaching.

B. Biotechnology in Agriculture—New Tools for the Oldest Science

With the discovery of the chemical structure of the genetic code of life some 30 years ago and the subsequent development in the past 10 years of gene-splicing techniques:

- Living organisms can be harnessed for the production of large quantities of specific biological products.

- Sexual reproduction can be bypassed in the transfer of specific desired traits between plants, animals, and microorganisms.

• DNA, that master molecule of heredity, can now be studied close up in ways not imagined only a few years ago.

These new abilities, along with other advances in such areas as microculture, cell fusion, regeneration of plants from single cells, and embryo recovery and transfer, are creating vast new opportunities all across the agricultural sciences. The tools of biotechnology are being applied to viruses and bacteria, to insects and weeds, to plants and animals, in all stages of their life cycles from replication through aging.

Improving Our Ability to Manipulate Genetic Material

Agricultural scientists increasingly speak a common language, centering on the cell—the basic unit of life. The critical importance of single cells lies in the fact that they are the units into which engineered genes are likely to be introduced—by transfer, by cell fusion, by microinjection. Microculture of organs, tissues, and cells also offers the potential for rapid screening of large populations in the earliest stages of growth.

Major efforts are being placed on finding ways to culture single cells from a wide number of agronomic plants and to regenerate them into whole organisms with the genetic message intact and expressed properly. In animals, embryonic single cells—fertilized eggs—may well be the recipients for gene transplants. Techniques such as embryo recovery, splitting, and transfer, whose development had little or nothing to do with the new biotechnology techniques, are playing critical roles in genetic engineering efforts.

Other new and powerful techniques now make it possible to determine much more quickly the precise chemical makeup of genes and their protein products, condensing into days what might have once required years to accomplish. Genes can also be located in their chromosomal packages relative to one another much more easily than in the past. More difficult, however, is the identification of the mechanisms regulating gene expression—what turns any given gene's activity on or off. We know very little about these controls which ensure that genes for a specific activity are operating when and where they are supposed to for proper growth and maintenance of the organism. A great deal of basic knowledge must be assembled regarding these controls and other interactions going on within and among cells before the improvement of plants and animals through gene transfer can be intelligently accomplished.

Understanding Defense and Messenger Mechanisms

A number of research areas in agriculture are being looked at today to see if and how new biotechnologies can be used to solve problems not approachable before. For example, new techniques now allow much more detailed studies of the defense systems in plants and animals than was ever possible in the past. New knowledge of the immune system in animals promises improved approaches for disease and parasite control and faster, more accurate diagnosis. More effective ways for increasing the plant or animal's own genetic resistance to pests and other stresses are envisioned. Con-

versely, improved techniques for sabotaging the defense systems of insects, weeds, and other pests also seem possible.

A growing understanding of how the chemical messengers we know as hormones operate as intermediaries in growth and development processes also promises more progress in an area that has been studied extensively and has seen much progress in the past.

Use of Model and Simulation Systems

Model systems and computer simulations are being developed specifically for agricultural research, and more are needed. The fruit fly, for example, has served as an invaluable model for the study of genetics, but models based on the physiology of agronomically important insect pests, such as the tobacco hornworm, are also needed. Petunia and wild tobacco make excellent laboratory plants, but corn, rice, soybean, potatoes, and wheat are also examples of model systems important to agriculture. Information will have to be assembled on each of our agronomically important crops in any event before gene transfers involving them are practical.

Applied and basic research in agriculture are so intimately intertwined in the biotechnologies that many practical spinoffs may be put on line while fundamental inquiries continue to pursue the basic knowledge necessary to make wide-ranging applications possible. Payoffs are aimed at increasing the efficiency with which we produce our food and fiber; increasing the quality of our farm products for markets at home and abroad; and increasing our storehouse of fundamental knowledge on which the next round of major advances in agriculture will be built.

C. Information Systems and Communication Technology

When the United States shifted from an agriculturally based economy to one based primarily on goods and services derived from an industrial economy, agriculture adjusted its farming practices to take advantage of these changes. U.S. agriculture is once again faced with major changes occurring in the economy, as we shift from a primarily industrially derived economy to one based on the production, processing, distribution, and utilization of information. Continued advances in communication and information technologies will revolutionize the ability to manipulate and communicate information.

Scientific and Extension Applications

The new tools provided by information and communications systems will provide individuals with ready access to current data for improving the management and productivity of their operations. Electronic mail will enable scientists to make daily contact worldwide with colleagues working in the same research area to discuss the most fruitful approaches to problems. When necessary, a scientist will be able to bring worldwide expertise to bear very quickly on problems which would benefit from a cross-disciplinary approach. And of course, each researcher will be notified daily of new projects and online publications in his or her area of interest. At some point, the

researcher might even have access to a colleague's laboratory notebooks as they are electronically updated.

We have sufficient experience with modeling to know that it is effective. The Agricultural Research Service has developed several models—including the Universal Soil Loss Equation (USLE); Chemicals, Runoff, and Erosion from Agricultural Management Systems (CREAMS); and Simulation of Cotton (SIMCOT)—that simulate major components of agricultural systems. Other organizations have developed extremely useful economic and management models for agricultural systems. Through state-based networks, such as Computerized Management Network (CMN), Agriculture Computer Network (AGNET), TELPLAN, and Fast Agriculture Communications Terminal Systems (FACTS), Extension has made diverse models available to farmers, agricultural producers, homemakers, community leaders, and youth.

Applications on the Farm

At the beginning of a new day, farm and ranch operators will be advised by their home terminal which actions are necessary to maximize daily operations. The terminal may even sound an alarm during the night if conditions sensed by the system move outside the bounds of acceptable limits. Livestock health will be automatically logged each day based on signals transmitted by embedded sensors monitoring heart rates, metabolism, and growth. Grain elevators will be driven by computer-operated robots. Weather data from the county satellite dish will be anlayzed at home using microcomputer programs. Available farm workers will be located by searching the migrant harvesting database; cost per hour will be negotiated by electronic mail. Operators will search the computerized database for research results on new crop varieties that would be well-suited for the particular soil and climate conditions found on their farms. Readouts from the automated irrigation sensors will keep the operators advised of moisture requirements. These are only a few examples of the many possible applications. An application of computerized farming was described in a recent article (Sept. 21, 1983) in the Wall Street Journal entitled: "Cows on Midwest Farm Get Automatic Reward for Giving More Milk."

Support Activities

The initial impact of these trends will be to confront end-users of agricultural information with a bewildering variety of databases, systems, and technologies. The need for information specialists to assist end-users will be extensive. It is also time to institute quality control factors to guarantee the most appropriate formatting, programming, and quality data at the input end. Information specialists can assist users when the information is accessed, but controls are needed on the amount and quality of data that enter the system.

Another need is to train people in the use of these tools. Training is needed to encourage computer literacy among professionals and among adult and youth clientele. Agricultural agencies also need to encourage expanded use of satellite networks to provide greater educational opportunities to local clientele.

The U.S. agricultural system has long known that ready access to the right information at the right time is the key to success in managing inputs, production, marketing, distribution, and consumption of food and fiber. The adopting of improved agricultural techniques continues to be limited by constraints such as access to capital, awareness of appropriate technology, and awareness of feasible alternatives. Emerging information technologies hold the key to getting the right information to the right people at the right time and thus helping producers overcome current constraints in the American food and fiber system.

D. Scientific Requirements for Maintaining Technology

Modern agriculture is a highly technical industry comprising hundreds of thousands of relatively small individual firms, producing hundreds of food, feed, and fiber commodities locally adapted. Production agriculture is site-specific, and technologies must be adapted to individual soil and climatic conditions. The usefulness of many agricultural technologies is in proportion to the proximity to the site for which they were developed.

Maintaining and Updating Agricultural Technologies

Technologies, like all man-made tools, age and become obsolete. This is true of physical technologies like dams and roads; it is true of mechanical technologies like trains, tractors, and combines; and it is true for biological technologies such as medical practices, plant varieties, livestock breeds, and pesticide uses. Biological systems are intrinsically dynamic.

- The average useful lifetime of a new plant variety is about 10 years. Change in wheat yields from 1875 to 1975 provides one example. The cumulative gain in productivity for the first 20 years was only 3.1 bushels per acre. Since then the gains in productivity have been substantial and future projections suggest continued increase. The first improved wheat variety was released by the New York Agricultural Experiment Station in 1920. Wheat yields have doubled (from 19.2 to 39.3 bushels per acre) in the four decades from 1935 to 1975. Improvements in culture technologies such as fertilizers, pesticides, and machinery accounted for about 50 percent of the increase and genetic improvements accounted for the other 50 percent.

- Some technologies depreciate more rapidly than others. Technologies developed for the control of insects and diseases are especially prone to rapid depreciation and obsolescence. Nature's propensity for new genetic combinations, combined with prolific reproduction and heavy selection pressure, can cause rapid change in the genetic composition of the resultant pest population. When that occurs, control technologies must be updated or replaced.

Meeting Unforeseen Threats

Unforeseen events that may arise and threaten food, fiber, and forest-product technologies fall into three major categories: natural disasters, food and environmental safety concerns, and control of insect and disease pests.

• Soon after the eruption of Mount St. Helens in Washington State on May 18, 1980, agricultural experiment stations, cooperative extension services, and the Agricultural Research Service and Forest Service of USDA responded to public concerns over the ash deposits. Information was gathered from all sources, chemical and physical analyses of the ash were conducted, and solutions to help alleviate the problems caused by the eruption were recommended. Products such as timber were salvaged, and the adverse effects on crops and livestock were minimized.

• Food and feed supplies may be contaminated by accident or by naturally occurring toxins. Guarding against contamination requires human resources who are familiar with agriculture, biology, and chemistry, and who have access to the analytical instruments to provide constant vigilance.

• The devastating impact of insects and disease on man's food supply is as old as recorded history. Swarms of locust and epidemics like the Irish potato blight remain a haunting specter. Agriculture has an arsenal of technologies to help combat insect and disease pests. The enemy is always time. One reason that U.S. agriculture has been so effective in combating pests is because the knowledgeable scientists and extension specialists who are working on these problems are dispersed across all crop and forest regions.

The base required to maintain and improve current technologies and meet unforeseen threats is proportional to the level of the technology. As a technology becomes more complex and specific, more scientists and technicians are required. In agriculture, the complexity is enormous, requiring knowledge and skills in many individual subject-matter areas, and knowledge of the interactions when several technologies are combined into a production system.

E. Equipment and Facilities

Scientists in publicly supported institutions have traditionally provided most of the new research ideas and innovative leadership in science, which in turn has stimulated industrial technology and business development and advanced the frontiers of knowledge for our society. However, the equipment and facilities needed to support this research and leadership are becoming progressively more sophisticated and, therefore, expensive. In addition, recent reports have underscored the problem of obsolescence of scientific instruments in publicly supported laboratories for basic research and the concomitant reduction in support for purchase or renovation of instruments. The need for new or improved facilities presents a quite different situation, but is related to the housing and effective use of the instrumentation.

Instrumentation—Needs and Maintenance

Instrumentation will be needed for two major purposes: (1) to conduct research and (2) to train people. These needs will be nearly identical for graduate student training, while the level of instrumentation-sophistication needed for undergraduate training will usually be less. Future projections about instrumentation must also consider the

acute problem of securing trained personnel to operate and maintain the more complex instrumentation, whether for research or teaching.

In the American Association of Universities report (1982) to the National Science Foundation, the investigating committee reported that support facilities of government laboratories surpassed those of university labs, and the best industrial labs surpassed, to a startling degree, all aspects of research support seen at university labs. Scientists who were principal investigators on grants responded to a questionnaire (Dr. M. Berliner, NSF study entitled "Status of Research Instrumentation in the Plant Sciences," June 1982) that their most urgent need was the replacement of equipment bought 15 to 25 years ago. Repair, maintenance, and updating were next in order of priority.

With the shrinking dollars available for purchase and maintenance of instrumentation, investigators report an increasing need to seek support from multiple sources simply to maintain a constant level of activity in research projects. This effort is costly because large amounts of time and ingenuity are expended in writing the multiple grants, thus diverting valuable time from research.

Instrumentation needed for basic research over the next 20 to 30 years will often be built upon some of the same principles as those in current use, but the practical details and modifications to increase resolution and efficiency may change decisively as the state of the art advances. For example, plasmid DNA can be spun down in an ultracentrifuge with the new vertical rotor in 4 hours; previously it required 48 hours or longer. Such time savings not only expedite the research but increase dramatically the life of the ultracentrifuge. New, unique instruments also will be invented, some combining principles from several technologies—lasers, fluorescence spectrometry, and computer automation, for example. The reference document contains a list of anticipated equipment needs for a modern molecular biology lab. To be properly equipped requires a significant investment.

Facilities—Needs and Maintenance

The Joint Council on Food and Agricultural Science, in their January 1981 Report to the Secretary of Agriculture, indicated that USDA research facilities had space for 647 additional scientist years (SY). State land-grant institutions had an overall deficit of 965 SY's of office and laboratory space. Unfortunately, surplus space in federal facilities does not easily lend itself to meeting space needs of the states because of differing geographical location and because of limitations in the design of the facilities for which the research was intended. Often the surplus space would require expensive renovations in order to fit the space needs of other federal research programs. Despite these difficulties, analysts of this situation see more opportunities for sharing that should be pursued.

New communications systems make distances less important. Distances between research, extension, and teaching facilities no longer affect programs as they would have 30 years ago. In the future, geography will probably become less significant, with the exception of field and environment testing.

Repairs and maintenance in publicly owned research facilities are not always up to date with respect to OSHA standards, other federal and state standards, and standards found in private institutions. Inadequate operating funds at many locations have led to neglect of proper maintenance and timely repair, resulting in deteriorating of existing facilities. Renovation needs for both federal and state facilities are substantial. Federal programs required renovation for 820.7 SY's or 18.4 percent of their 1978 scientific population. State programs required renovation for 1249.5 SY's or 18.7 percent of their 1978 scientific population.

V. Performers of Research, Extension, and Higher Education

Most descriptions of publicly supported science and education programs in agriculture focus on the USDA, land-grant universities, and others. Although useful as a preliminary introduction, such descriptions fail to capture both the numerous ways in which these segments interact and the emerging importance of non-land-grant colleges and universities and the private sector (Feller et al., 1983). The "performers" of public agricultural research and education are located in state and federal institutions with varying administrative and program structures. Each institution or agency has a specific role. Interaction among "performers" grows out of program linkages and coordination developed through cooperative planning and shared institutional processes. This informal set of linkages provides for communication among scientists and promotes developments that have helped establish a system-wide approach in research, extension, and higher education. State-managed science and education programs must and do respond to needs expressed at state and local levels, but they also address regional, national, and international issues because of the implications these issues have for the local agriculture industry. The federally-managed science and education programs are directed primarily at regional, national, and international issues, but the findings often have implications at state and local levels, where producers and consumers make their individual decisions.

A. Research

Land-grant performers include 56 Agricultural Experiment Stations (including Departments of Forestry, Colleges of Veterinary Medicine, and Home Economics). In addition there are 16 separate schools of forestry, Tuskegee Institute, and 16 of the 1890 colleges. The USDA provides support, reviews, and national coordination for these state-managed programs through the Cooperative State Research Service. The main internal performers of research in USDA are the Agricultural Research Service, Forest Service, and Economic Research Service. The Office of International Cooperation and Development has the responsibility for coordinating the Department's international science programs.

The related research efforts occurring in other federal agencies are, in general, being done for different purposes than the research conducted by state Agricultural Experiment Stations and USDA. A relationship exists because there are interlocking interests

and the research often depends on similar scientific disciplines, i.e., biology, chemistry, and economics. When the National Institutes of Health fund a study in human diseases, Colleges of Veterinary Medicine often have a strong mutual interest. When the Fish and Wildlife Service investigates population trends of endangered species, the habitat conditions existing on farms are often an important causal element. About 65 percent of the agriculture-related research funded by non-USDA federal agencies is conducted through contracts and grants with private firms, universities, and other institutions. The remaining work is conducted in federally operated laboratories. A more complete analysis of these activities is available in a report prepared by USDA (March 1982) entitled "Inventory of Research, Extension, and Higher Education related to Food and Agriculture, conducted by Federal agencies other than USDA."

The non-land-grant public university system consists of more than 350 state colleges and universities. Of this group, approximately 65 have programs in agriculture and forestry. The primary mission of these colleges and universities is the provision of undergraduate and master's level education. Reported research activity for agriculture-related programs amounted to $14 million in the 1980-81 academic year. Most of the funds came from non-USDA federal agencies, industry, and state governments.

By far the largest segment of the overall food, fiber, and forestry research and development (R & D) system is the private sector. This sector's activities are poorly documented, but recent surveys have developed expenditure estimates and discussed the nature of the research. In 1979, the National Science Foundation estimated private-sector R & D expenditures at $1.8 billion. A more recent estimate puts it at $2.5 billion. By their own admission, managers of private-sector R & D emphasize product or market-oriented studies. At the farming level, 75 percent of the R & D expenditures are for pesticides, drugs, and farm equipment—areas of unique concern to suppliers of farm production inputs. At the post-farming level, the emphasis is on food processing, machinery, and packaging. In general, industry performers have little motivation for expending R & D resources on either natural resource and environmental issues or to better understand basic biological processes. They generally depend on public-sponsored research for this information. Unless R & D results can be patented and used in a company product fairly quickly, private companies are reluctant to finance scientific studies.

One example of the motivating force of patents is the expanding interest of the private sector in genetic engineering. Since altered organisms can now be patented, both small and large companies are expanding their R & D efforts in this area. Several joint ventures are either underway or being planned between universities and private companies.

Research Funds by Source

State Agricultural Experiment Stations (1982)[1]	*Amount (Mil)*
USDA Funding	
Hatch and McIntire-Stennis	174.6
Grants and Contracts	39.5
Other	5.7
Total USDA	214.8
Other Federal Grants and Contracts	122.0
Total Federal	341.8
State Support[2]	714.6
Total Federal and State	1,056.4
USDA Performers (1983)[1]	
Agricultural Research Service	454.4
Forest Service	105.0[3]
Economic Research Service	38.9[3]
Office of International Cooperation & Development	3.3
Others	20.2
Total	621.8
Related Efforts in Other Federal Agencies (1981)[1]	
National Oceanic & Atmospheric Administration	72.4
National Institutes of Health	173.4
Interior (Primarily Geological Survey, Fish and Wildlife Service, and Bureau of Reclamation)	106.9
National Science Foundation	24.5
Tennessee Valley Authority	19.5
Others	124.1
Total	520.8[4]

[1]Indicates year of funding.

[2]Includes state appropriations (primary source), sales of products, and industry grants and contracts.

[3]Represents research-related part of agency budget.

[4]The $122.0 million shown for state Agricultural Experiment Stations is included in this figure.

B. Extension

Cooperative Extension was designed as a partnership of USDA and the land-grant universities. State legislation enabled local governments or organized groups in the Nation's counties to become a third partner in this educational endeavor. There are professional extension staff in nearly all of the Nation's 3,150 counties. In addition, 1 1/2 million volunteer leaders work with the full-time personnel. At the national level, 100 professionals within USDA direct federal fund allocations, coordinate National initiatives, and provide program leadership. The partners in Cooperative Extension are interdependent, yet each has considerable autonomy in funding, staffing, and programming. The system is characterized by two-way communications between those who work for Extension and those who use the information; thus, researchers and educators have an early awareness of problems.

In addition to the educational programs of the Extension Service, other USDA agencies perform informational and technology-transfer activities. These include the Soil Conservation Service, Forest Service, Food and Nutrition Service, and others. These information transfer activities are integral parts of those agencies' missions and thus are not separate budget items. At the county, state, and national level there are active coordination efforts between these agencies and the Extension Service. Similar coordination exists with non-USDA federal agencies that have information/extension type programs.

The level of extension-related information activities in the private sector is not known. This lack of data, however, should not be construed to mean that these activities are insignificant. An important component of selling any product is educating the buyer on its proper use and the expected benefits. Many manufacturers, processors, and distributors maintain a close, cooperative relationship with agricultural research and extension workers. A similar relationship exists with private consultants who sell their services to agricultural and forest landowners and managers. This synergistic relationship is viewed now, and for the future, as appropriate and beneficial to all parties involved—particularly to the consumers of the final product.

C. Higher Education

At least 136 U.S. universities and colleges offer degree programs in the food and agricultural sciences. A little more than half of these institutions are land-grant schools. Most of the non-land-grant schools are publicly supported, but are not direct partners with the Department of Agriculture. The number of graduates in agriculture-related sciences in 1981 were: 28,665—bachelor's; 5,503—master's; and 1,039—Ph.D's. Based on data from the Department of Education's National Center for Education Statistics, these totals reflect the following specialty areas: veterinary medicine, agriculture and natural resources, human nutrition, plant pathology, and agricultural engineering. At the bachelor's level the split between land-grant and non-land-grant institutions is 62.5 percent and 37.5 percent respectively. At the master's level it is 67.0 percent and 33.0 percent. Most Ph.D degrees in agriculture-related sciences are granted by land-grant institutions.

Extension Funds by Source

Cooperative Extension (1983)[1]	Amount (mil)
USDA Support	
Smith-Lever, 1890's, & Tuskegee	259.8
Food and Nutrition Education	60.4
Other	3.0
Total USDA	323.2
State	388.0
County	161.9
Non-Tax Source	27.1
Total (Federal, State, County	900.2

Related Extension Efforts in Other Fed. Agencies (1981)[1]	
Energy Department	20.3
Labor Department	11.8
Tennessee Valley Authority	14.8
Others	13.5
Total	60.4

[1]Indicates year of funding

Major financial support for higher education in agriculture, particularly at the undergraduate level, comes from state governments. In public universities, faculty compensation is often established by the legislatures or negotiated between the state government and the university. Articulation of public university roles within a state is also an important role of state government; that is, which universities will offer what kind of agricultural education. Development of agricultural curricula and the granting of degrees remains the province of the individual institutions, and accreditation is provided by regional and national associations.

Including cost of instruction, academic services, and maintenance and operation of the physical plant, institutions of higher education spend close to *$1 billion* each year to train people in agriculture and natural resources. This estimate includes tuition contributions of students but no other student expenses (e.g., books, room, and board). This amount represents a considerable commitment by residents of the states to provide a trained pool of professionals that make contributions at local, state, and national levels of the economy.

D. Why Public Investment?

The primary reason for public investment in agricultural science and education programs has been that, in many areas, *incentives for the private sector are inadequate* (Ruttan, 1982). The rationale for this statement is based on the difference between private and public goods (Mueller, 1979).

Characteristics of Private Goods

When a private firm can capture most or all the value of a good in the marketplace, it has the incentive to produce and distribute the amount demanded at a market clearing price. For goods such as bread, cars, and television sets, the purchaser has exclusive use of the benefits. In addition, the value is not shared by someone outside the immediate household. A similar condition exists when a private firm develops and sells an improved pesticide, animal vaccine, or piece of farm equipment and is able to protect the value of that improved technology with a patent. The farmer who purchases this item has exclusive use of the improved product and there are little or no benefits, derived from its use, shared with other farmers. In both of these situations the exchange of value is, to a major degree, within the control of the producer and consumer of the good. To be considered a private good, that is a necessary condition.

Characteristics of Public Goods

For public goods like national defense, environmental concerns, and major portions of agricultural science and education programs, the performers and users cannot feasibly withhold the benefits from others. In other words, those who do not purchase or pay for any of the public or collective goods cannot be excluded or kept from sharing in their consumption. For example, a person paying no federal taxes is protected from a foreign enemy just as well as a person who does pay taxes. A beautiful mountain scene can be enjoyed both by a passerby and by the landowner who protects its natural character. The contribution of a trained scientist, in agronomy for example, cannot possibly be captured fully by sellers and buyers in the marketplace. The benefits derived from developing improved farming practices (that increase plant output per acre and conserve soil resources) serve future generations as well as today's. When scientists transmit the nature of those improved agronomic practices to the next generation of scientists and managers, another benefit is being realized.

There are obviously different degrees of public and private goods. The above examples are at opposite ends of a continuum. However, when a good tends toward being more public than private, the need for public investment becomes more obvious. When a good has more characteristics of a private good, it should be left to the forces of the marketplace. *In the mixed economic system that exists in the United States, both public and private performers must carry out their respective functions or the total society suffers.*

Returns on Investments

When describing the theoretical foundation of public goods, Samuelson (1959) stated "No decentralized pricing system can serve to determine optimally those levels of collective actions." This conclusion is especially appropriate when it comes to investment in scientific programs. Evenson, Waggoner, and Ruttan (1979) have shown significant returns for past public investments in agricultural research and education—from 45 to 130 percent—the kind of returns private business would relish. These figures provide strong evidence for the public nature of these investments. *If the benefits could have been captured by a private performer, those kinds of returns would have attracted private funds.*

The split between public and private investment in future scientific programs will differ somewhat from the past. Changes in patent laws (the 1980 Chakrabarty decision opened up the opportunity to patent living organisms), increasing size of commercial farms, and increased dependence of farming on industrially produced inputs all affect the publicness and privateness of research and education programs in agriculture (Evenson, 1983).

Appendix A
Country/Region Coverage

North Africa/Middle East	—The northern tier of the African countries, and the Middle Eastern countries, including Turkey and Afghanistan.
Sub-Saharan Africa	—All the countries of Africa (including South Africa) except the northern tier (Algeria, Egypt, Libya, Morocco, and Tunisia) which are in North Africa/ Middle East.
EEC-10	—The member countries of the European Economic Community.
Other Western Europe	—The Western European countries who are not members of the European Economic Community.
USSR	—A single-country region.
Eastern Europe	—All of the Eastern European countries, including Yugoslavia.
South Asia	—Bangladesh, Bhutan, India, Nepal, Pakistan, and Sri Lanka.
East Asia	—Japan, Brunei, Burma, East Timor, Hong Kong, Indonesia, Republic of Korea, Laos, Macau, Malaysia, Maldives, Philippines, Singapore, and Thailand.
Asian Centrally Planned Economies	—China (including Taiwan), Kampuchea, Democratic People's Republic of Korea, Mongolia, and Vietnam.
Oceania	—Australia, New Zealand, and the other islands of Oceania.
Latin America	—Mexico and all the other Central and South American countries.
North America	—The United States and Canada.

Source Documents

I. Needs Assessment Reference Document

A. Introduction
W. Joseph Lanham, Needs Assessment Task Group and Program Leader, Economic Development, ES/USDA.

B. Overview of Long-Term Needs for Food, Fiber, and Forest Products
Kenneth R. Farrell, Fred H. Sanderson, Trang T. Vo, and Michael F. Brewer, Resources for the Future, Washington, D.C.

C. Long-Term Problems and How Science and Education Can Impact Those Problems
Soil, Water, and Air Resources—Albert R. Grable, National Program Leader, ARS/USDA; and William E. Larson, Head, Department of Soil Science, University of Minnesota.

Forest, Range, and Wildlife—Richard A. Skok, Dean, College of Forestry, University of Minnesota; Elwood L. Shafer, Staff Assistant to the Deputy Chief for Research, FS/USDA; Gale Wolters, Range Scientist, FS/USDA; and James E. Miller, Program Leader, Fish and Wildlife, ES/USDA.

Crop Production and Protection—John S. Boyer, ARS/USDA, University of Illinois; and John P. Mahlstede, Assoc. Dean, College of Agriculture, Iowa State University of Science and Technology.

Animal Production and Protection—Terry Crawford, ERS/USDA; Terrence M. Curtin, Dean, College of Veterinary Medicine, North Carolina State University; Sheila Gillette, Needs Assessment Task Group, ARS/USDA; Dixon Hubbard, Program Leader, Animal Sciences, ES/USDA; Bernard Jones, Dean and Director, College of Agriculture, University of Nevada; Dyarl King. ARS/USDA; Robert Oltjen, U.S. Meat Animal Research Center, Clay Center, Nebraska; and Walter Woods, Head, Dept. of Animal Sciences, Purdue University.

Processing, Marketing, and Distribution—Leo Polopolus, Chm., Dept. of Food and Resource Economics, University of Florida; Arnold E. Denton, Vice President, Research and Technology, Campbell Soup Co.; Harold S. Ricker, Deputy Director, Market Research and Development Div., AMS/USDA.

Human Nutrition—Patricia B. Swan, Professor, Dept. of Food Science and Nutrition, University of Minnesota; and Robert O. Nesheim, Vice President, Science and Technology, Research, and Quality Assurance, Cambridge Plan International, Monterey, California.

Family and Consumer Programs—Katherine S. Tippett, Family Economics Research Group, ARS/USDA; and Jane L. McCullough, Dept. of Home Economics and Consumer Education, Utah State University.

Youth, Family, and Community Development—W. Robert Lovan, National Program Coordinator, Community Decision Making Structures, ERS&ES/USDA; Adger B. Carroll, Asst. Director of Cooperative Extension Service, Natural Resources and Public Policy Programs, Michigan State University; and W. Joseph Lanham, Needs Assessment Task Group and Program Leader, Economic Development, ES/USDA.

Agricultural Policy—Kenneth C. Clayton, Director, National Economics Div., ERS/USDA; and Bruce W. Gardner, Professor, Dept. of Agricultural Economics, University of Maryland.

International—Ernest L. Corley, Acting Senior Deputy Administrator, OICD/USDA.

D. Needs of Science and Education System To Continue Solving Problems of U.S. Agriculture

Developing Scientific Expertise in Agriculture—Kenneth W. Reisch, Assoc. Dean, College of Agriculture and Home Economics, Ohio State University; Allan D. Goecker, Asst. Dean, School of Agriculture, Purdue University; and Geri C. Richmond, Needs Assessment Task Group, and Management Analyst, OGPS/USDA.

Biotechnology in Agriculture—New Tools for the Oldest Science—Alice F. Skelsey, President, WRD Associates, Inc., Annandale, Virginia, with the aid of a group of scientists.

Information Systems and Communications Technology—Jane Roth, Needs Assessment Task Group and Program Analyst, OGPS/USDA; Tom Tate, Program Analyst, ES/USDA; and Sam Waters, Assoc. Director of National Agricultural Library.

Scientific Requirements for Maintaining Technology and Developing Human Capital—Charles B. Rumburg, Needs Assessment Task Group, Plant and Animal Science, CSRS/USDA.

Equipment and Facilities—Larry W. Moore, Assoc. Professor of Plant Pathology, Dept. of Botany and Plant Pathology, Oregon State University; and W. Joseph Lanham, Needs Assessment Task Group and Program Leader, Economic Development, ES/USDA.

Joint Council on
Food and
Agricultural Sciences
FY 1987 Priorities for
Research, Extension, and
Higher Education
A Report to the
Secretary of Agriculture

The Joint Council on the Food and Agricultural Sciences was established in 1977 to encourage and coordinate research, extension, and higher education activities in the food and agricultural sciences. This role was strengthened in the Agriculture and Food Act of 1981, which directed the Department to improve the planning and coordination of research, extension, and higher education within the public and private sectors and to relate the federal budget process to the overall functioning of the system.

The Joint Council initiated four reports intended to improve the overall effectiveness of the food and agricultural system.

A long-term **needs assessment** (20-30 years) for food, fiber, and forest products and the research, extension, and higher education requirements to meet the identified needs. (This task was assigned to the Secretary of Agriculture in the Agriculture and Food Act of 1981. He requested the Joint Council to fulfill this responsibility). The needs assessment report was prepared and published in two separate documents. One is the *Reference Document: Needs Assessment for the Food and Agricultural Sciences* and the other is the *Summary: Needs Assessment for the Food and Agricultural Sciences.*

A **five-year plan** to reflect the coordinated goals and objectives of the research, extension, and higher education community. This report was published in 1984 and will be updated biannually.

An **annual priorities report** on research, extension, and higher education, which presents the Joint Council's priorities for the next fiscal year, the required financial support, and suggested federal, state, and private sector roles. This report will be completed by June 30 of each year.

An **annual accomplishments report** which specifies the ongoing research, extension, and higher education programs and respective accomplishments, along with expectations for the future. This report will be completed by November 30 of each year.

These four reports are inter-related although each is published separately. They constitute an overall strategic planning process which provides the food and agricultural science system with a means of assessing short-term and long-term future needs and reflecting on past accomplishments. They provide a foundation for planning the most effective and efficient means for meeting the future demands for food, fiber, and forest products. These four reports also offer a continuing mechanism by which the research, extension, and higher education programs can assess future needs.

The symbol appearing on the front cover represents the purpose of the Joint Council (i.e., to improve planning and coordination among research, extension, and higher education) and the cooperative character of the food and agricultural science system within federal, state, and private organizations.

Joint Council on Food and Agricultural Sciences

Secretariat:
Rm. 321 A, Admin. Bldg.
U.S. Department of Agriculture
Washington, D.C. 20250

June 28, 1985

Honorable John R. Block
Secretary of Agriculture
Washington, D.C. 20250

Dear Mr. Secretary:

We are pleased to submit the annual priorities report on research, extension, and higher education, prepared by the Joint Council on Food and Agricultural Sciences in accordance with Title XIV of the Agriculture and Food Act of 1981 (Public Law 97-98).

The Joint Council prepared this report after considering 86 priorities submitted by the National Committees and Regional Councils of the Joint Council.

We have selected five science and education areas to be emphasized as budget plans are developed for fiscal year 1987. In order of priority, they are:

1. Increase Agricultural Profitability Through Management
2. Improve Water Quality and Management
3. Expand Biotechnology Efforts on Plants, Animals, and Microbes
4. Develop Necessary Scientific and Professional Human Capital
5. Improve Human Nutrition and Understanding of Diet/Health Relationships

While it is important to focus on these key areas in FY 1987, continued funding for the base programs in research, extension, and teaching must also be emphasized. Significant and special thrusts in the key priority areas, along with strong base programs, will assure the continued technological progress necessary for a strong, healthy agriculture.

Sincerely,

Orville G. Bentley
ORVILLE G. BENTLEY

Research, extension, and higher education programs in food and agriculture have important roles in shaping the future of both U.S. and world food, fiber, and forest product supplies. Continuous planning, both short- and long-term, is necessary if we are to use resources most efficiently and effectively. The Joint Council on Food and Agricultural Sciences has a congressionally-mandated role to develop plans for the future. The Council prepares the annual Priorities Report as a guide for those who develop the federal budget and for others in science and education who seek guidance concerning important national problems currently facing the food and agricultural system. A longer term look at the most urgent problems needing solution is presented in the Joint Council Five-Year Plan.

In developing the FY 1987 Priorities Report, the Joint Council requested and received from the National Agricultural Research Committee, the National Extension Committee, and the National Higher Education Committee a statement and ranking of urgent priorities. The Regional Councils of the Joint Council presented regional views of significant priorities.

In May 1985, the Joint Council identified five major priorities for FY 1987 science and education programs. The Joint Council recognizes the importance of strong base programs in research, extension, and teaching and urges the continuance of support for these programs. Those priorities selected for special emphasis are particularly appropriate because of specific problems now facing agriculture and/or because of opportunities for important advances in these areas.

Recommended National Priorities

1. Increase Agricultural Profitability Through Management

Profitability has always been an important component of U.S. agricultural and forestry enterprises. To help the producers of food and fiber cope with the current difficult economic climate, the science and education system needs to develop multidisciplinary research and education programs focused on increasing farm and forest profitability. Attention should be directed to optimizing profits through better integration of production, management, and marketing strategies, including new uses for farm products, and to developing realistic family and business goals. Agricultural producers who face critical operating decisions need help in evaluating available alternatives. Producers also need assistance in developing management systems, including control and management of plant and animal pests and diseases, that will use human resources efficiently and produce maximum profit. Low-cost, efficient production systems will help U.S. agriculture remain competitive in world markets.

2. Improve Water Quality and Management

Protecting water resources and using them efficiently continue to be important concerns for agriculture and forestry. Natural sources of water are being threatened by toxic chemicals and atmospheric pollutants. In the arid West there is a need to utilize water supplies more efficiently through the application of feasible watershed management practices. Improved irrigation efficiencies can reduce both energy requirements and the importation of waterborne salt. Attention should be directed to assessing the impact of soil, water, and atmospheric pollutants on livestock and crops and to improving the

understanding by public officials and citizens about the nature of water resources. There is a need for increased understanding of relationships between crop production systems and the quality of ground and surface waters.

3. Expand Biotechnology Efforts on Plants, Animals, and Microbes
Through biotechnology, plants, animals, and microbes can be improved or modified to enhance their benefits to society. Recent innovations in genetic engineering techniques hold great promise for revolutionizing agriculture, forestry, microbiology, biology, and medicine. Molecular geneticists and conventional plant breeders are highly dependent upon a resource of genetic diversity, which must be assembled, maintained, and made readily accessible through an efficient system to develop the unique, productive organisms necessary for a stable, plentiful, and high-quality supply of food, feed, fiber, and forest products, and for the development of new uses for these products. Research should be expanded on transfer, expression, and regulation of individual genes and gene systems and on acquiring and conserving the maximum range of genetic diversity by appropriate sampling, collection, and preservation procedures.

4. Develop Necessary Scientific and Professional Human Capital
Today's American agriculture is a high-technology industry characterized by rapid and continual changes in methods of production, large investments in research, and an ongoing need for a highly qualified cadre of scientists and professionals to meet increasing demands for food and agricultural products. To achieve the goals necessary to meet projected needs, immediate action must be taken to increase the development of scientific and professional human capital. Steps which will enhance this activity are: expansion of pre- and post-doctoral fellowship programs, development of a national, computerized, higher education information system, implementing faculty revitalization programs, and strengthening curriculums.

5. Improve Human Nutrition and Understanding of Diet/Health Relationships.
Today's consumers are bombarded with nutrition advice from many sources. Some of this advice is unreliable, expensive, and not in keeping with the recommendations of nutrition scientists. Abundant production alone, without attention to quality factors, is not sufficient to assure consumer acceptance of products and adequate returns to farmers. Better linkage is needed between plant and animal production/processing as they relate to human nutrition requirements. More emphasis should be directed to determining human nutrient requirements under both normal and stressful conditions and their relation to long-term health factors. Improved technology to prevent, detect, and remove natural and environmental toxins and pathogens from food products is also needed. Consumers must be educated about problems faced by agricultural producers, and producers must be informed about desires of consumers for food products that enhance nutritional well-being.

Other Topics Considered

The Joint Council also discussed several other important priorities. They included: sustaining soil productivity; improving forest and range productivity; encouraging energy conservation; enhancing efficiency of agronomic and horticultural crop production; collecting, preserving, evaluating, and enhancing germplasm; reducing impacts of pests on plants; reducing impacts of atmospheric deposition and water pollutants on plants; augmenting livestock and poultry production efficiency; improving management of animal diseases and pests; and increasing aquatic food production.

Other priority items considered were: improving food quality and safety; improving family financial management; encouraging home horticulture; improving agricultural policy analysis; improving economic information on U.S. agricultural trade; expanding domestic and international markets for agriculture and forest products; expanding use of electronic communications/computer systems; increasing public education on agriculture; and developing volunteer leadership.

Narratives describing these additional prionties can be found in Appendix 2, pages 23 to 40.

Resources Needed

The active pursuit of priorities identified by the Joint Council will require both redirection of current programs and new funding. The Joint Council feels strongly that additional federal support is well justified. The opportunity to develop new human resources, new knowledge, and agricultural technology has never been greater. The need to transfer this new knowledge and technology to producers and consumers is equally great. As needs and priorities change, the agricultural science and education system has demonstrated that it can redirect programs. The potential for redirecting programs is not without limits, however, because the system must maintain a broad program base to continually update current technologies, respond to unforeseen emergencies, and educate future managers and scientists.

I. Introduction

Research and education are future-oriented activities—the research of today is developing the technology of tomorrow. Therefore, research and education policies and priorities must be based not on the emotions of the moment, but rather on the perceptions of future needs.

The time horizon for this report is the remainder of the century. During this period, adequate production would not be a problem if the demands for food and fiber were limited to the U.S. market. But our agricultural and forest product markets are global and increasingly interdependent.

The past three decades of global economic development have provided a major stimulus to U.S. agriculture. Production expanded by nearly 70 percent and the United States became a dominant supplier of grains and oilseeds in world trade. The growth in demand for U.S. grains, oilseeds, and cotton for the remainder of this century is likely to depend primarily on expansion of foreign demands. Growth in demand for meat and milk probably will depend largely on developments in domestic markets. These trends imply that U.S. agriculture will be increasingly export-dependent and increasingly cash-crop dependent.

This growing dependency on exports and cash crops has important implications for the selection of priorities in the agricultural sciences. On the production side, U.S. producers face increasing competition in the marketplace from producers in other countries. More efficient production technologies and improved management systems are required to keep U.S. production costs competitive in world markets.

Agricultural markets, always subject to the uncertainty of weather and government policy changes, are growing increasingly complex. This situation requires the development of specialized policies and agreements. In addition, improved transportation and storage technologies will be needed to maintain commodity quality and meet various foreign import regulations.

The growing dependency on cash crops means greater pressure on soil and water resources. Improved crop yields will tend to lessen the use of marginal lands for cash crops. Research in soil productivity will improve management of soil nutrients and provide more effective and affordable soil erosion control technologies. Improved water management techniques will increase the efficiency of use of limited groundwater supplies.

Finally, the outlook for the remainder of the century is for modest but steady improvements in the living standards of Americans. Rising living standards and educational levels will strengthen the consumer trends of the recent past. People will continue to be concerned about food quality, nutrition, and food safety. The proportion of meals eaten away from home and the demand for convenience foods can be expected to continue to increase. Concern about environmental issues is also likely to remain strong.

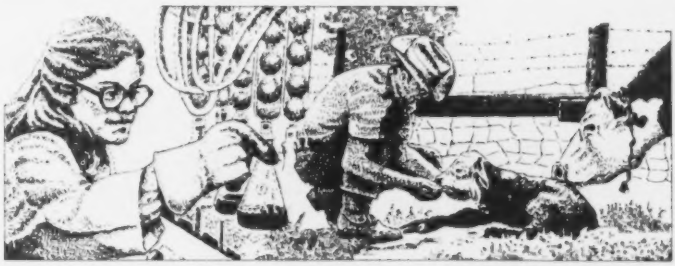
We can, therefore, look forward to the year 2000 with both concern and hope. Concern, because many food, fiber, and forest production, processing, and marketing problems lie ahead. Hope, because our research, extension, and higher education system has the capacity—if properly supported—to supply solutions to these problems.

This report discusses the most important issues and priorities for United States agricultural research, extension, and higher education for fiscal year 1987. In addition, it suggests the natural, human, and financial resources required to address these priorities. The Joint Council on Food and Agricultural Sciences, which was designated by Congress to prepare this report, includes members from: land-grant and other universities, representing research, extension, and higher education; foundations; producers; consumers; and USDA and other federal agencies.

The FY 1987 Priorities Report includes:

- A description of five critical national food and agriculture priorities identified by the Joint Council on Food and Agricultural Sciences as those on which the science and education system should focus its attention.
- A statement indicating the level of both federal and non-federal financial support of science and education in FY 1984 and an indication of needs in FY 1987.
- Descriptions of a number of additional important areas of emphasis for science and education. Although these areas were not included in the highest category of priorities, the Joint Council considers them to be of real significance to food and agriculture progress.
- A listing of priorities submitted to the Joint Council by National Committees, Regional Councils, and regional functional committees.

II. Selecting the National Priorities



To develop this FY 1987 Priorities Report, the Joint Council requested and received from the National Agricultural Research Committee, the National Extension Committee, and the National Higher Education Committee a statement and ranking of urgent priorities. The Regional Councils of the Joint Council presented regional views of significant priorities.

In addressing the science and education priorities for FY 1987, the National Committees and Regional Councils gave careful consideration to the current status of the food and agricultural system and to the problems and concerns of agriculture. Each Committee and Council ranked the priorities judged to be of greatest importance and submitted them to the Joint Council for consideration.

Priorities of the Research, Extension, and Higher Education Committees of the Joint Council[1]

National Agricultural Research Committee

The National Agricultural Research Committee (NARC) submitted 21 priorities for consideration by the Joint Council. These priorities came from priority rankings independently developed by the four regional agricultural research committees and submitted to the NARC.

The NARC pointed out that the U.S. public agricultural and forestry research system, representing a coalition of more than 100 units, is committed to serving high-priority national, regional, and state needs. The research system is highly adaptable and can mobilize and redirect resources to support new research agendas when needed.

Collectively, the agricultural and forestry base programs of each research agency constitute the foundation of the national system. It is crucial to the welfare of agriculture that state and federal funding give high priority to ensuring that those base programs remain broad, diverse, and dynamic, and that they are continually updated. From those base programs flow the knowledge and technology needed to meet most new challenges.

[1]A complete list of the priorities of the three National Committees of the Joint Council is in Appendix 1, Table 1.

National Extension Committee

The National Extension Committee (NEC) submitted 26 priorities to the Joint Council. The first 11 were given especially high ratings. The NEC priority rankings were developed by considering inputs from the State Extension Directors/Administrators, the National Extension Advisory Council (NEAC), and the federal Extension staff in response to a list of 29 topics submitted to them.

Regions generally agreed on priority rankings, but variation is apparent among several potential priorities. These include Integrated Reproduction Management, ranked higher in the Southern and Western Regions; Local Government, ranked higher in the North Central Region; Forest Resource Management, ranked relatively higher in the Southern and Western Regions; and Grazing Land Management, ranked relatively higher in the Western Region. Human Resource Development and Small and Home-Based Business are relatively more important among the 1890 institutions.

National Higher Education Committee

The National Higher Education Committee (NHEC) identified five priorities for emphasis in FY 1987. The NHEC emphasized the importance of attracting the brightest minds from the diminishing pool of students into the food and agricultural sciences and of providing the Nation with a continuing pool of well-educated agricultural scientists and professionals. Also emphasized was the importance of continued faculty renewal programs to maintain extant faculty on the cutting-edge of modern science. The development of necessary scientific and professional human capital must be a primal concern of the U.S. agricultural complex. Technology does not advance without professionals. Research is neither performed nor extended to industry without scientists. Steps must be taken now to deal with the increasing shortage of highly trained food and agriculture professionals and scientists. If action is delayed, the problem will intensify and have a detrimental impact on the entire food and agricultural system.

Priorities of Regional Councils and Committees[2]

The four U.S. geographic regions have different and distinct agendas dictated by environmental, social, and economic factors. Priorities were developed by the Regional Councils and Committees and by high-level agricultural decisionmakers within regions.

Northeast Region

Continuing changes in the Northeast agriculture, food, and forestry industries are affecting the educational and scientific institutions that service and support them. Some crop,

[2]Priorities of Regional Councils are shown in Appendix 1, Table 2. Regional research, extension, and teaching priorities are listed in Appendix 1, Tables 3, 4, and 5 respectively.

livestock, and forest production has shifted from the Northeast to other regions. The Northeast Regional Council submitted 10 priorities to the Joint Council, headed by basic research and scientific expertise development. Profitability in agriculture and farm financial and business management were the top two priorities of the Northeast Region Extension Directors.

North Central Region

More than 40 percent of the Nation's farm cash receipts are generated in this region. The region is an important producer of red meat, dairy products, food and feed grains, and oilseed crops. Major issues affecting this region are decline in farm profitability, soil erosion, competition for land use and resources, and export and commodity prices. The North Central Extension Directors placed farm financial and business management as their top priority, followed by profitability in agriculture. The North Central Agricultural Research Committee ranked biotechnology as the highest priority, followed by agricultural profitability.

Southern Region

Southern producers, like those in other U.S. regions, are faced with markedly lower profits. Soil erosion is a problem, and there is an urgent need to increase efficiency by focusing on plant and animal production systems. The Southern Regional Council submitted 13 priorities. The first was improved water management and water use efficiency; and second was improved animal health and reproduction. Extension Directors in the Southern Region gave profitability in agriculture and farm financial and business management their first and second rankings. The Southern Regional Research Committee placed the greatest emphasis on biotechnology, followed by soil and water management.

Western Region

The states in the Western Region have very diverse climates, topography, and agricultural commodity production. Water is a key to the West's economy. The Western Regional Council submitted 11 priorities for consideration by the Joint Council. Improving the use and conservation of water was the top priority of this Council, followed by product and market development. The Western Directors of Extension ranked agricultural profitability as their most urgent priority, followed by farm financial and business management.

Selecting the Top Priorities

After the Joint Council received the priority lists, the staff combined items covering similar areas. The consolidated list was first ranked in order of priority by Joint Council members individually. Subsequently, the Council met to discuss the proposals and select the five highest priorities for FY 1987.

III. Recommended National Priorities

Technologies that farmers need in order to remain competitive are costly and complex. Those who lack the capital and expertise to adopt a new technology early enough to maintain a competitive edge may find themselves in serious financial straits. The U.S. food and agriculture science and education system, which has been envied throughout the world, must face the challenges of the current economic climate. It must expand and refine past successes to help agricultural producers achieve more economical production. At the same time, the technology base for improving agricultural production efficiency must be increased.

Recognizing these factors, the Joint Council selected five priorities for FY 1987.

1. Increase Agricultural Profitability Through Management

2. Improve Water Quality and Management

3. Expand Biotechnology Efforts on Plants, Animals, and Microbes

4. Develop Necessary Scientific and Professional Human Capital

5. Improve Human Nutrition and Understanding of Diet/Health Relationships

A brief discussion of the importance of each of these priorities and the roles of research, extension, and higher education in contributing to solutions of problems is presented below.

Increase Agricultural Profitability Through Management

Agricultural profitability, always of importance to our Nation's food and fiber producers, is of particular concern in today's economic climate.

To help food and fiber producers cope with problems of depressed profit levels, the science and education system needs to develop and deliver research and education programs focused on increasing farm and forest profits. These programs require a multidisciplinary systems approach aimed at optimizing profit through better integration of

management, production, and marketing strategies. The **goal is maximum profit**, which does not necessarily imply maximum production. Emphasis must be on overcoming the current short-run financial crises and maintaining the long-run viability of agriculture.

The current situation developed as producers responded to growing exports, rising prices, accelerating inflation, and low real interest rates during the 1970's by **borrowing heavily to invest** in new labor-saving machinery and facilities, new production technologies, more land, real estate improvements, and increased use of fertilizer and chemicals. With falling exports, lower prices, higher interest rates, and lower incomes during the 1980's, the **increased debt burden has increased costs** and greatly limited management flexibility.

The critical decisions facing farmers and ranchers today are those dealing with farm management, operating efficiency of the total production system, financial planning, debt management, risk appraisal, family financial management, and economic survival. **Producers need help** in appraising their available resources, evaluating alternative opportunities and enterprises, and developing production systems that are viable, realistic, and economically feasible. The impact of farm finances on personal and family finances and of family goals on business goals needs to be understood and resolved.

Improved production and protection systems are needed on a continuing basis to improve efficiency and profitability for agronomic and horticultural crops, livestock and poultry, rangeland and forests. More effective methods for control and management of plant and animal diseases, insects, weeds, parasites, nematodes, and other pests and health hazards must be developed that are effective, economically sound, and environmentally acceptable.

The productive capacity of U.S. agriculture and forestry exceeds current domestic and foreign demand, with grain carryover continuing at burdensome levels. The weak demand for agricultural and forest products, especially for export, has had a depressing effect on commodity prices. A key to future profitability is **continued expansion of domestic markets including new uses for farm products, and recovery of the declining export market.** Continued research is needed to assure the improving productivity necessary to maintain the long-term viability of the agricultural sector by providing reasonably priced food, fiber, and forest products for the domestic market and competitiveness in foreign markets.

To restore more profitability in the food and agriculture system, more effective research, extension, and teaching are needed to:

- Develop total production systems to help producers optimize farm profits through better integration of production, management, and marketing strategies.
- Help producers analyze problems on an enterprise and commodity basis to identify profitable and unprofitable enterprises and determine the most economically viable production systems.

- Help producers understand the relationships among production decisions, financial management, risk management, and marketing alternatives and their impact on profitability.

- Encourage producers to adopt improved production practices aimed at cutting the cost of inputs and reducing losses while increasing product quality and improving net incomes.

- Expand the market for agricultural and forest products by increasing domestic utilization and consumption and by improving the ability of U.S. agriculture and forestry to compete in international trade.

- Help farmers, ranchers, and other rural land owners identify personal, family, and business goals and understand the financial impact of their decisions.

Improve Water Quality and Management

Protection and efficient use of water resources continues to be an important concern for agriculture and forestry. Natural sources of water are being threatened by toxic chemicals and atmospheric pollutants. Analytical capabilities to detect pollutants have greatly outstripped research on the effects of ingestion of minute concentrations of toxic chemicals. Thousands of disposal points for industrial and other toxic wastes are located in rural areas. These disposal sites pose a potential but unknown long-term threat to rural residents, livestock, plants, wildlife, and waterways.

Thirty-four states have identified agricultural nonpoint source pollution as a major cause of the failure to achieve state water quality goals. Twenty-nine states have identified nonpoint source pollution of groundwater as a major concern and have cited agricultural pesticides and septic tank seepage as primary causes. Much of the potential for pollution can be reduced through changes in soil-tillage practices.

In the arid areas of the Western States, there is a need to increase available water supplies through the application of improved watershed management practices on forest and rangeland. Improved management practices are also required to prevent salinity damage to highly productive crop-producing areas. Improved irrigation efficiencies can reduce both energy requirements and the importation of waterborne salt. A recently increased concern is the safe and economical disposition of drainage waters, some of which are contaminated with toxic metals such as selenium.

Improved research and teaching programs are needed to:

- Assess the impact of water and atmospheric pollutants on livestock, crops, and forest and aquatic ecosystems.

- Formulate improved management systems that optimize the use of chemicals, minimize erosion, and reduce the movement of pollutants to surface and ground water.

- Develop economical practices to increase water yields from forests and rangelands.
- Increase understanding of relationships between crop production systems and the quality of ground and surface waters.
- Improve soil and water management systems to reduce the impact of salinity in arid areas and to improve irrigation efficiencies.
- Design systems for the safe and economical disposal of contaminated irrigation waters.

Extension programs are needed to:

- Develop and implement coordinated interdisciplinary educational programs about the nature of our water resources; the importance of "pure" drinking water to human health and nutrition; the significance of water quality test data; the proper use, handling, and disposal of agricultural chemicals; the impact of various land uses; and the options for reducing pollution and keeping water safer for human use.

Expand Biotechnology Efforts on Plants, Animals, and Microbes

Biotechnology refers to the high-technology tools and techniques used in today's biological sciences. Through biotechnology, plants, animals, and microbes can be improved or modified to enhance their benefits to society. **Recent innovations in biotechnology and genetic engineering techniques** will likely revolutionize medicine, biology, microbiology, forestry, and agriculture. The techniques of plant cell and protoplast culture; plant regeneration; somatic hybridization; embryo transfer; and recombinant DNA approaches such as the identification, characterization, splicing, replication, regulation, and transfer of genes can be focused for improving plant, animal, and microbial species.

Studies of the structure and organization of genomes will require a major commitment to **developing germplasm collections.** The characterization of germplasm will lead to efforts to enhance the genetic makeup of organisms and to tailor production of specialty chemicals. Many of the recent biotechnological innovations are also applicable in the animal industries. Recombinant DNA and monoclonal antibody techniques can help characterize bacterial and viral antibody-antigen interactions and improve immunodiagnosis. In addition, they can enhance production of antigens and synthetic peptides as animal vaccines.

A diversity of improved genetic populations of plants, animals, and microbes will result in improved yield, quality, nutrient content, resistance to pests, response to adverse environmental stresses, harvest ratios, handling and storage, and compatibility with new production methods. Significant progress in this area will require development of the potential to **manipulate genomes rapidly and efficiently.**

Molecular geneticists and conventional plant breeders are highly dependent upon a resource of genetic diversity, which must be assembled, maintained, and made readily

accessible through an efficient system such as the National Plant Germplasm System (NPGS). The NPGS, a network of public and private workers and facilities, functions as the steward for the U.S. collection of plant germplasm.

Basic research studies will provide new knowledge and improve the fundamental understanding of cellular genetics and biology. These will serve as a base for further advances in biotechnology, assure continued growth in related sciences, and meet important agricultural and forestry needs. Areas of concern include: modification of the metabolite partitioning process, movement of nutrients into biological systems, development of specific hormonal entities, culture and regeneration of cells, development of microbes for processing of nutrient- and mineral-rich foods and feeds, and the subsequent development for farm products. Agricultural colleges and universities must consider making changes in curriculums to provide the necessary expertise.

The Division of Agriculture Committee on Biotechnology of the National Association of State Universities and Land Grant Colleges made an intensive study on "Emerging Biotechnologies in Agriculture". This publication emphasizes the importance of assessing **the potential biological and environmental impacts of releases of organisms containing recombinant DNA for agricultural uses.** it also focuses on the need to assign priorities in the biotechnology field.

Present research needs exist primarily in four areas:

- Structure, function, and organization of plant, animal, and microbial genomes.
- Transfer, expression, and regulation of individual genes and gene systems.
- Genetic control and molecular modification of growth, development, and resistance to physical and biological stresses.
- Preservation of the maximum range of genetic diversity.

Develop Necessary Scientific and Professional Human Capital

Modern agriculture is a high-technology industry characterized by rapid and continual changes in methods of production, large investments in research and technology transfer, and an ongoing need for a highly qualified cadre of food and agriculture scientists and professionals.

Historically, skilled and motivated high school students from agricultural backgrounds enrolled in "state of the art" agricultural colleges. After graduation, they entered agricultural industry or enrolled in graduate programs. Ultimately, these students became the scientists and leaders of the research and education system which undergirds our technological agricultural enterprise. The stability of this human capital base has deteriorated dramatically over the last decade. Between 1977 and 1983, baccalaureate

enrollments in agriculture at land-grant universities declined approximately 30 percent. During this same period, graduate enrollments diminished by 5 percent. Projections through the mid-1990's suggest a continuation of these trends. To some extent the decline may be attributed to demographic realities. However, between 1977 and 1982, total U.S. college enrollments were continuing to increase while agriculture enrollments were declining. Total U.S. college enrollments did not decrease until 1983. Hence the diminishing pool of college age youth cannot be the sole reason for declining enrollments in agriculture. Rather, we must recognize that the public's unidimensional "production" image of agriculture, combined with increasing competition from other disciplines, is contributing to the **reluctance of students to pursue degrees in the food and agricultural science disciplines.**

Agricultural expertise is vital to the security and well-being of this country. Our position as the lead Nation in agriculture requires an adequate scientific and professional human capital base. Several **national initiatives must be launched** jointly by the federal-state partnership, working cooperatively with the private sector, **to strengthen the food and agricultural sciences higher education system** as it competes with other disciplines, such as engineering and computer science, in the academic marketplace for outstanding students.

Competitive Graduate Fellowships and Research Apprenticeships

- Initiatives must be undertaken to attract and support outstanding science-oriented students. Specifically, the pre- and post-doctoral fellowship programs and the research apprenticeship program for high school students must be expanded and targeted to those areas with the most critical shortages of expertise.

National Information System for Higher Education Strategic Planning

- A comprehensive, computerized national information system must be further developed to provide baseline data for policy and program development, resource allocation, and program evaluation. This information system should include statistics such as enrollments, degrees conferred, employment demand for graduates, student financial aid, and faculty.

Strengthening of Institutional Capacities

- University faculties must be revitalized to assure continued program relevance. Innovative faculty developmental opportunities such as short-term sabbaticals and industry-government-academia exchange programs are needed to restore "cutting edge" science and technology to the agricultural classroom.

- "State-of-the-art" scientific equipment must be provided for instructional purposes to enhance higher education programs in the food and agricultural sciences.

- Curriculums must be strengthened if the system is to produce graduates at the forefront of knowledge and technology. Academia, government, and industry must cooperatively identify, prioritize, and promote needed curriculum improvements. Revision efforts must address not only the rapid expansion of knowledge but also the provision of experiences which will expand students' communications skills, decisionmaking competencies, agricultural ethics, and public policy analytical skills, as well as their ability to apply their specialized knowledge and skills in both the domestic and international arenas.

Improve Human Nutrition and Understanding of Diet/Health Relationships

Americans have access to more high-quality, moderately priced, safe and nutritious food products than any other people in the world. For many years we have taken for granted the availability of a plentiful supply of palatable, wholesome food. **Abundant production** alone, without attention to quality factors, **is not sufficient to assure consumer acceptance** of products and adequate returns to farmers. Farm products must be attractively presented to consumers with wholesomeness assured, quality maintained, and in accordance with market demand. Research and education efforts to improve quality and safety provide important linkages between production of high-grade agricultural products on one hand and consumption and human nutrition on the other.

In recent years, **public interest in nutrition, diet, and health issues** has been overwhelming. Today's consumers are bombarded with nutrition recommendations from many sources. Some of the recommendations are unreliable, expensive, and not based on well-documented nutritional facts. If this situation is not corrected, misinformation and confusion will continue to inundate the public. Nutrition education for consumers based on reliable research could have major implications for agricultural profitability and stability.

Quality assurance and hazard analyses are vital functions for control and protection by the food industry in the production, processing, packaging, storage, and distribution of agricultural products. Improved quality assurance makes sure that quality standards are met, contamination and deterioration are reduced, and shelf-life is extended to prevent product, nutritional, and economic losses. Good manufacturing practices and frequent safety inspections are necessary to ensure wholesome food.

Research has provided information addressing a number of perplexing questions. However, the metabolic relationship between nutrient intake and physiological response is exceedingly complex. Inadequate nutrition and improper dietary practices are contributing factors in various diseases and infant disabilities or mortality. Our knowledge of the relationships between nutrient quality and human genetic potential is scant, and our ability to alter naturally occurring food nutrients via biotechnology has barely scratched the surface.

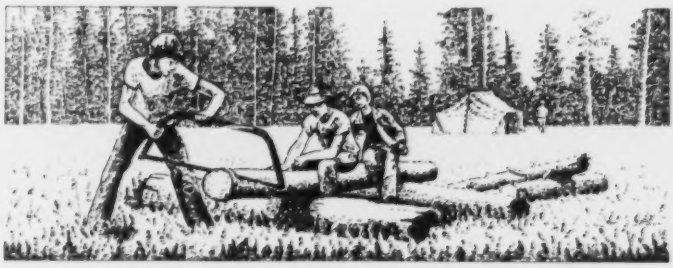
Research areas which need to be emphasized include:

- Determination of human nutrient requirements under both normal and stressful conditions and their relation to long-term health factors.
- Determination of the bioavailability of nutrients in foods.
- Investigation of the determinants of good dietary practices and educational strategies for promoting good nutrition.
- Assessing the effects of production and postharvest technology on quality, acceptability, and food safety.

Extension emphases are needed to:

- Formulate strategies for educating consumers about the realities of agricultural production and marketing as well as making producers aware of consumers' desires for products that enhance nutritional well-being.
- Establish communication among clientele, producers, processors, extension educators, researchers, and policymakers so that unified messages about nutrition and health can be evolved and supported.
- Educate the consumer on proper food storage and handling to maximize nutrient retention and food safety.

IV. Financial Support Needed for Priority Programs



Financial support for public research, extension, and higher education in the food and agricultural sciences is derived from many sources; however, state, local, and federal appropriations provide the major source of the sustained funding necessary for long-term commitments. Such long-term commitments are necessary for both technology development and human resource development. Priority programs are addressed through real increases in appropriations, by redirection of ongoing programs, and by contracts and grants.

While state-managed science and education programs respond principally to needs expressed at the regional, state, and local levels, they also address national and international issues. On the other hand, although federally-managed science and education progams are directed primarily at national and regional issues, the findings often can be utilized effectively at state and local levels, where producers and consumers make their individual decisions. Judgments about whether programs can be most effectively and efficiently performed by the public or the private sector are based on several criteria, among which are the intended recipients of the benefits and the potential market size.

The U.S. Department of Agriculture supported research and education programs in the food and agricultural sciences in the amount of $1.1 billion in fiscal year 1984. Expenditures were divided among several USDA agencies: Agricultural Research Service ($455.8 million), Economic Research Service ($43.7 million), Forest Service ($108.7 million), and Office of International Cooperation and Development (OICD) ($7.9 million). State agricultural experiment stations and state cooperative extension services received formula distributions from Cooperative State Research Service ($208.3 million) and Extension Service ($289.9 million), respectively. Higher Education Programs had a graduate fellowship program ($5.0 million) and supported resident instruction programs through the Morrill-Nelson Act ($2.8 million) in 1984.

Nonfederal support (mostly state and local government appropriations) for food and agricultural research and extension programs was $1.4 billion in fiscal year 1984. State funding for instruction by land-grant and other colleges and universities exceeded $1 billion.

Subject Matter	Research ($Mil.)		Extension ($Mil.)		Higher Education ($Mil.)	
	USDA	Nonfederal	USDA	Nonfederal	USDA	Nonfederal
	1984	1984	1984	1984	1984	1984
Natural Resources	207.8	129.7	12.2	34.9	0.5	
Crop Production and Protection	278.6	316.3	60.9	150.1	1.8	
Animal Production and Protection	148.0	237.6	35.6	87.8	1.2	
Processing, Marketing, and Distribution	126.4	70.4	36.8	40.3	2.1	
People and Communities	57.0	30.0	144.4	298.6	1.6	
Agricultural and Resource Policy	10.9	29.2	--	--	0.6	
Unclassified	0.1	0.2				
Totals	**828.8**	**813.4**	**289.9**	**611.7**	**7.8**	**>1000.0**

Other federal agencies also support programs related to food and agricultural research, extension, and higher education. The most recent estimate of this support, made in 1982, was $581.2 million.

The Joint Council feels strongly that additional federal support is well justified. The opportunity to develop new human resources, knowledge, and agricultural technology has never been greater. The need to transfer this new knowledge and technology to producers and consumers is equally great.

Appendices

Appendix 1

Priorities Recommended by the National Research, Extension, and Higher Education Committees, Regional Councils and Committees

Table 1. Priorities for FY 1987 in Agricultural Research, Extension, and Higher Education Submitted by National Committees[1]

National Agricultural Research Committee	National Higher Education Committee	National Extension Committee
1. Water quality and management	1. Expand the pre- and post-doctoral fellowships programs and research apprenticeship programs to attract outstanding students into food and agricultural specializations characterized by current/projected shortages of expertise.	1. Profitability in agriculture
2. Strengthen market penetration for current and new agricultural and forest products	2. Develop a national computerized higher education information system that provides essential data for strengthening policies and programs directed toward enhancing our food and agricultural higher education system.	2. Farm financial and business management
3. Sustaining soil productivity	3. Update and revitalize college and university faculty in the food and agricultural sciences	3. Water quality and management
4. Livestock and poultry profitability and product quality	4. Initiate an institutional strengthening grants program targeted toward improving higher education in the food and agricultural sciences.	4. Family financial management
5. Human nutrition	5. Promote needed curriculum revisions aimed at producing graduates at the forefront of knowledge and technology.	5. Human nutrition and health
6. Increase profitability of agronomic and horticultural crops		6. Marketing agricultural and forest commodities
7. Forest and range management		7. Youth development/lifelong education
8. Management of animal diseases and pests		8. Scientific expertise and human resource development
9. Integrated management systems		9. Crop management systems
10. Germplasm collection, preservation, evaluation, and enhancement		10. Livestock and poultry management systems
11. Competitiveness of U.S. agriculture and forest products in world markets		11. Soil conservation and productivity
12. Food quality and safety		12. Forest resource management and wood utilization
13. Management of plant pests		13. Family strength and well-being
14. Agricultural policy analysis under alternative monetary, fiscal, and trade policies		14. International development and trade
15. Human resource development		15. Volunteer development
16. Effects of air and water pollutants on plants		16. Integrated pest management
17. State-of-the-art equipment and facilities		17. Electronic communication/computers
18. Conservation and development of energy		18. Aquatic food production
19. Rural family and community resource management and economic development		19. Public education in agriculture
20. Aquatic food production		20. Home horticulture
21. International science interdependence		21. Economic and small and home-based business development
		22. Wildlife and fish management
		23. Local government and organization
		24. Natural resource and policy education
		25. Grazing land management
		26. Agricultural weather

[1]Priorities are listed in rank order.

57-279 O - 87 - 32

Table 2. Priorities for FY 1987 in Agricultural Research, Extension, and Higher Education Submitted by Regional Councils[1,2]

Northeast Regional Council	Western Regional Council	Southern Regional Council
1. Basic research	1. Improve the use and conservation of water	1. Improve water management and water use efficiency
2. Scientific expertise development	2. Product and market development	2. Improved animal health and reproduction
3. Human nutrition	3. Improve agricultural profitability through farm management	3. Develop recombinant DNA and monoclonal antibody techniques for characterization of bacterial and viral epitopes and to aid immunodiagnosis and production of antigens and synthetic peptides as vaccines
4. Sustaining soil productivity	4. Recruitment of high-quality students	4. Plant germplasm collection, maintenance, enchancement, and evaluation
5. Water quality and management	5. Improve quality of higher education	5. International supply, demand and price relations for major U.S. export commodities
6. Food processing and marketing efficiencies	6. Improve production systems and resource management	6. Development of improved cropping and management systems for important agri-ecosystems
7. Family resource management	7. Identify interrelationships among diet, human nutrition, and health	7. Development of animal production and management systems for improving acceptability and market quality
8. Alternate production systems	8. Expand research and education in biotechnology	8. Reduced soil erosion from wind and water
9. Improved public education delivery systems	9. Enhance family well-being through improved resource management	9. Postharvest handling, storage, and processing for maintenance and improvement of crop quality and utilization
10. Forest productivity and best management practices	10. Improve technology for the use and conservation of energy	10. Development of effective pest management systems
	11. Enhance human potential through youth and volunteer development	11. Increase the number of trained personnel to support the Nation's agricultural industry
		12. Development and utilization of engineering systems for efficient crop production
		13. Innovative, safe, and nutritious food products for modern society

[1]Priorities are listed in rank order.
[2]Priorities were not submitted by the North Central Regional Council.

Table 3. Ranking of Priorities by the Regional Agricultural Research Committees[1]

Northeastern	North Central	Southern
1. Basic research	1. Biotechnology of plants, animals, and microbes	1. Biotechnology for the improvement of crop and animal species
2. Human nutrition and food safety, quality, and acceptability	2. Enhancing long-term profitability of agriculture	2. Engineering systems for soil and water management for efficient crop production
3. Animal productivity	3. Integrated crop production systems	3. Pest management systems for crops
4. Soil, water, and energy resources	4. Basic research on the biology of agricultural plant and animal species and their pests	4. Animal reproduction
5. Forest productivity and development	5. Improve insect and disease occurrence and control models in plants	5. Germplasm development and enhancement
6. Plant productivity	6. Reduce impact of diseases in livestock and poultry production	6. Control of animal diseases
7. Economics of agriculture and forestry	7. Improve production systems for agronomic and horticultural crops	7. Improved cropping and management systems
8. People and communities	8. Short-term adjustments in production systems to improve economic efficiency, minimize risks, and increase net farm income	8. National and international supply and demand, price relations and marketing systems for agricultural products
Western	9. Improving livestock and poultry production systems	9. Animal production and management systems
1. Expand supplies, protect the quality, and improve the use and conservation of water	10. Expand markets for high-quality agricultural products	10. Biology, culture, and management of forests and timber-related crops
2. Biotechnology and genetic engineering	11. Improving human nutrition	11. Crop modeling for more efficient crop management systems
3. Increase productivity and efficiency of western food and fiber systems	12. Support of graduate programs to train future scientists	12. Postharvest handling, storage, and processing for maintenance and improvement of product quality
4. Improve the safety and nutritional quality of the Nation's food supply	13. Meeting growing needs for new high-tech research equipment and replacing obsolescent equipment	13. Improved acceptability and market quality of animal products
5. Improve knowledge and technologies for agricultural management and policy decisions	14. Resources to maintain current programs	14. Impact of air and water quality on crop production
6. Expand supplies and improve the use and conservation of energy	15. Enhance profitability of forests and forest products	15. Aquatic food production
		16. Agricultural, monetary, and foreign trade policy with emphasis on agribusiness

[1]Priorities are listed in rank order.

Table 4. Ranking of Priorities by Extension Directors[1]

Northeast	North Central
1. Profitability in agriculture	1. Farm financial and business management
2. Farm financial and business management	2. Profitability in agriculture
3. Human nutrition and health	3. Family financial and business management
4. Family financial management	4. Human nutrition and health
5. Marketing agriculture and forest commodities	5. Soil and water conservation and management
6. Youth development/ lifelong education	6. Youth development/ lifelong education

Table 5. Higher Education Priorities[1] for FY 1987 Submitted by Regional Higher Education Committees[2]

Northeastern	Western
1. Strengthen efforts to recruit academically outstanding students into food and agricultural sciences higher education programs	1. Attract outstanding science-oriented students into college and university degree programs in the food and agricultural sciences
2. Develop a national computerized higher education information system	2. Develop a national computerized information system that will provide essential data for analyzing and strengthening our Nation's food and agricultural higher education system
3. Expand faculty development opportunities	3. Modernize instructional facilities and scientific equipment
4. Provide for state-of-the-art scientific instrumentation for instructional purposes	4. Revise university curriculums to produce graduates at the forefront of knowledge and technology
5. Revitalize university curriculums across the food and agricultural sciences	5. Revitalize college and university faculty in the food and agricultural sciences

[1]Priorities are listed in rank order.
[2]North Central and Southern Regions did not submit higher education priorities.

Appendix 2

Other Important Priorities

Nineteen additional priorities considered by the Joint Council, all of which are important to continued progress in the U.S. food and agricultural system, are described in this Appendix. Some of the information presented here has also been used in the narratives for the top five priorities. **The narratives presented in the subsequent pages are grouped according to subject-matter area and are not arranged by priority.**

Sustain Soil Productivity

Soil resources are a primary determinant of the productivity of our crop, range, and forest lands. Accelerated soil erosion by wind and water is an important national problem. In addition to long-term degradation of the soil resource base, erosion creates sediment which causes large and continuing offsite damages. The Conservation Foundation estimates that annual losses to recreation, fisheries, water facilities, and water users from agriculturally related sediment total $4 billion per year.

Productivity problems related to erosion include the loss of effective water-holding capacity and plant nutrients and organic matter as well as surface-soil attributes which enhance infiltration of water and seed-bed characteristics.

Both conservation tillage practices, which have been widely adopted because of strong economic incentives (lower labor, machinery, and energy requirements), and shelterbelts help reduce soil erosion from wind and water.

The success of conservation tillage practices provides an opportunity to promote the concept of soil conservation, fertility management, and input-conserving practices as parts of new and improved plant production systems. This situation presents a challenge for the coordinated efforts of basic and applied researchers, teachers, extension workers, and soil conservationists.

Research and teaching programs are needed to:

- Improve understanding of the relationship between erosion and soil productivity.
- Trace the movement and impact of sediment within fields, forests, and watercourses.
- Refine methods for estimating onfarm and offsite damages from erosion and sediment.
- Improve understanding of the relationship between soil nutrients and tillage practices, including studies of the ecology of soil microorganisms.
- Design complementary research activities to improve crop, range, and forest land management by developing new, lower-cost, resource-conserving plant production systems.

Extension programs are needed to:

- Cooperate with other government agencies and private organizations to motivate farmers and other land managers to increase the rate of adoption of new technologies that optimize the use and conservation of soil resources.
- Develop and disseminate information about the impact of wind and water erosion on agricultural land and on offsite facilities, recreation, and water users.
- Promote the concept of new plant production systems designed to accelerate the adoption of cost-effective, economically feasible soil conservation practices to reduce the impact of soil erosion on both producers and consumers and encourage the shift of marginal lands to conservation uses.

Improve Forest and Range Productivity

Most of the extensive acreages of forest and range resources (71 percent of the total U.S. land area) can be managed to produce more useful products through multiple use. These products include timber, pulpwood, forage, water supplies, wildlife habitat, fuels, minerals, and recreation opportunities.

Future timber and pulpwood availability will be influenced by the productivity of nonindustrial forest land, conversion of forested lands to other uses, and the increased use of wood for fuel. Fifty-eight percent of the Nation's productive forest land is held by 7.7 million priv of forested lands to other uses, and the increased use of wood for fuel. Fifty-eight percent of the Nation's productive forest land is held by 7.7 million private landowners. Current production of private forest lands is less than half the potential. Better management practices designed to increase production and lower costs can help to realize this potential in an increasingly competitive international market for wood products.

Improved management and emerging technology in silvicultural and protective practices—genetically improved trees, integrated pest management, reforestation, thinning, fertilization, and use of system analysis—have the potential to double or triple the production of major softwood species.

Rangelands are also being managed below their physical potential. The ecological status of grazing lands is improving; however, 38 percent is still in poor condition and 16 percent remains in very poor condition. Encroachment of weeds and bushes is a problem in 300 million acres. Soil erosion is a serious problem in many locations.

Research, extension, and teaching programs are needed to:

- Use basic biotechnology techniques for development of genetically improved, pest- and disease-resistant trees and range plants.

- Find and improve range grasses that will prosper in subregions with varying combinations of climate and soil characteristics.
- Develop low-cost practices for protection of forests from insect, disease, and fire losses.
- Improve harvesting and processing operations to increase product yields, lower costs, and lessen environmental damages.
- Develop improved low-cost management practices for range ecosystems to increase production and utilization of forage plants while protecting the soil resource.
- Increase landowner knowledge of more productive and profitable management practices and markets for wood products.
- Improve landowner returns from management of forest and range lands for hunting or other recreation uses.
- Improve public understanding of forest and range resources and multiple-use potentials in order to reduce user conflicts and improve long-term productivity.

Encourage Energy Conservation

The production, transportation, and processing sectors of U.S. agriculture account for 16.5 percent of all energy used in the United States. Imported fuels are the largest single category contributing to the current record-breaking trade deficit.

The stunning escalation of petroleum prices in the 1970's provided incentives both for consumer and industrial conservation and for research into improved, energy-efficient processes and alternative sources of energy. In agriculture, there has been a flurry of interest in alternative hydrocarbon fuels, biomass, and the development of more efficient equipment and cropping practices, such as reduced tillage and more efficient use of fertilizer.

Recent declines in the prices for petroleum and other fossil fuels stem in large measure from the spectacular successes in energy conservation in the United States and other industrial countries, and, to a lesser extent, the slowdown in global economic activity. The fall in prices has appeared to remove some of the immediate urgency to consider energy a leading problem. This attitude is short-sighted, however, because: (1) energy is a major input into agricultural production and deserves attention as a part of the general search for ways to reduce production costs, (2) the decline of nuclear energy and the increasingly serious environmental problems associated with coal can be expected to put upward pressure on prices for petroleum and natural gas, and (3) developable supplies of petroleum and natural gas are limited and world production may peak in the foreseeable future. U.S. petroleum production has already peaked.

Continuing research activity will be essential to facilitate long-term adjustments in agricultural energy use and production.

Research programs are needed to:

- Develop more energy-efficient systems consistent with overall efficient systems for producing, harvesting, processing, and transporting agricultural products.
- Continue development and evaluation of the feasibility of using agricultural resources to provide alternative energy sources.

Extension programs are needed to:

- Encourage the adoption of cost-lowering and energy-conserving technologies in the production, processing, packaging, and distribution of agricultural and forest products.

Enhance Efficiency of Agronomic and Horticultural Crop Production

The inability of some agronomic and horticultural crop production systems to provide commodities at competitive prices has created a crisis for many producers. This situation is exacerbated by instability of prices and exports, severe cash flow problems, relatively high interest rates, and stable or declining asset values. U.S. agriculture is at a critical junction, particularly since the outlook for the next 2 to 5 years is for continued instability of production capacity, plus a slower rate of growth in demand for crops.

An accurate identification of the needs of these producers is urgently needed. The resources required to address these needs must be assembled and programs must be initiated to solve the key problems that are deterrents to future crop production efficiency.

A multidisciplinary research, extension, and teaching approach is needed, on a commodity and farm basis, to develop total production systems designed to improve efficiency of agriculture.

Research is needed to:

- Explore ways to enhance the competitiveness of U.S. agriculture in the world market.
- Identify and improve marketing opportunities, with effective alternatives.
- Incorporate biotechnology approaches in conventional plant breeding to reduce input costs by developing improved varieties which will suffer fewer adverse effects from disease, insects, nematodes, temperature and water stress, and competition from weeds.

- Use genetic engineering to alter plant structures and shapes to improve harvesting and maturing processes and possibly reduce production costs and improve quality.

- Develop ways to modify existing cultural practices, such as crop rotations and tillage procedures, in order to enhance profitability.

Extension and teaching programs are needed to help present and potential producers, and their supporting industries, to:

- Analyze farm records to identify efficient and inefficient production practices, enterprises, and alternatives.

- Clarify the relationships between crop management decisions, risk management, and marketing alternatives and their impacts on crop production efficiency.

- Identify short- and long-term production trends and their implications.

- Adapt to changing demands, production practices, and farm policies.

- Explore opportunities for alternative crops and/or for diversification.

Collect, Preserve, Evaluate, and Enhance Germplasm

The expanding human population is destroying the plant genetic diversity that it must have to feed itself. Genetic diversity is the basis for selection of new germplasm and an essential tool in genetic improvement. Changing land-use patterns, brought on by man's need for living space and material goods, are destroying habitats of primitive crop varieties and their wild relatives, the principal sources of genetic diversity. Increases in production efficiency come from better pest resistance, improved reaction to adverse environmental stresses, increased yield and nutritional value, and development of the quality characteristics which are preferred in the marketplace. Diverse genetic material must be assembled, maintained, evaluated, and made available through a strong national plant germplasm system.

The National Plant Germplasm System (NPGS) provides the coordination necessary for collecting, preserving, evaluating, and enhancing needed germplasm. The NPGS directly affects the scientific community, agricultural producers, processors, and consumers. Crop hazards such as diseases and insects change over time in their ability to attack originally resistant varieties; production systems are altered by environmental and energy constraints; and consumer demands and needs for products with improved nutritional value change in response to improved dietary information and economic considerations. A large assortment of reserve genetic material is necessary in order to alter crops in response to these changes.

Every U.S. citizen is affected by adequate supplies of plant germplasm, because reasonably-priced high-quality food comes mainly from the more efficient varieties and

hybrids. Because of the "bred-in" protection against disease and insect pests, drought, cold, and other production hazards, the consumer is assured a stable food supply and less environmental pollution.

Research efforts must be intensified:

- To acquire unique plant germplasm, since plant species and varieties are becoming extinct at a rate unprecedented in man's history.
- To evaluate acquired germplasm to determine its potential value to crop breeders and other users.
- To enhance selected genes so the user community can benefit from the valuable germplasm identified.

Reduce Impacts of Pests on Plants

There is an increasing need to develop more effective methods for pest management, taking into consideration the effects on environmental quality as well as the economic impacts. Insects, plant diseases, weeds, nematodes, and vertebrates cause losses greater than 30 percent during the production, marketing, and storage of agricultural and forestry crops in the United States. Producers spend more than $10 billion each year in efforts to control these pests.

Integrated pest management has been extremely useful for pest control. Reduction of the adverse impacts of pests on plants is best attained with a systems approach based on a fundamental understanding of the pest-host relationship. This approach utilizes selective chemicals, biological control agents, resistant plant varieties, and sound cultural practices. The systems that emerge through this approach will be economically feasible and environmentally acceptable. Biotechnology will provide new options for improving the effectiveness of pest management while reducing costs.

Research is needed on:

- The biology and interactions of pests, their hosts, and natural enemies and on the unique characteristics of the metabolic pathways of pests.
- Pest population dynamics, genetic diversity, movement/dispersal, and behavior.
- Refined diagnostic, sampling, and forecasting techniques.
- The benefits and risks of using pest control chemicals which have critical agricultural and forestry uses.

Extension and teaching are needed to:

- Develop curriculum changes that provide in-depth knowledge and understanding of the basic biologies of crop plants to be protected and of pests to be controlled.

- Train pesticide applicators to enable them to use pesticide products safely and dispose of unused quantities in ways that have minimal detrimental effects on the environment.

- Train county extension agents in the principles and practice of integrated pest management techniques.

Reduce Impacts of Atmospheric Deposition and Water Pollutants on Plants

Air and water quality must be improved in order to reduce adverse impacts on crops, forests, ornamental plantings, and off-site water needs. Pollutants from agricultural chemicals, industrial emissions, and naturally occurring sources enter the atmosphere through volatilization, drift, and wind erosion. Materials from waste disposal sites leach into surface and groundwater systems and percolate into aquifers. These processes have caused a deterioration in the quality of our air and water resources and are threatening the economic health of agriculture and forestry in some areas of the United States.

The economic well-being of agricultural crop and forest production, particularly in the Western States, requires a continuing supply of large amounts of water at specific times. In some cases, water used for irrigation has become laden with salts and agricultural chemicals, creating serious crop phytotoxicity problems for subsequent users.

Since the 1940's, there has been increasing concern about the effects of air pollutants, particularly ozone and oxides of sulfur and nitrogen, on agricultural and forest resources. During the past 10 years, that concern has focused in part on the acidic precipitation, or acid rain, which is affecting crops, forests, soils, and surface waters.

Acid rain has become a polarized, emotional national issue. Before it can be resolved, it will be imperative to gain a better understanding of the total chemistry of the atmosphere. For example, acid precipitation must be considered along with gaseous and dry particulate pollutants.

State, federal, and industry scientists already are cooperating to determine effects of atmospheric deposition on crops, forests, soils, surface waters, and materials such as buildings, bridges, and monuments. A relatively small funding base supports crops effects research. Funding for forestry effects research has increased significantly because of unexplained declines in forest stands in the Southeast and Northeast. Pollutants have been implicated in these declines.

Research and extension programs are urgently needed on:

- Interactions of atmospheric deposition with other air pollutants, such as ozone and oxides of sulfur and nitrogen, that affect the growth of crop and forest species.

- Technology for monitoring total ambient atmospheric chemistry, integrating wet-deposition and dry-deposition concentration measurements over major agricultural and forestry regions.

- Alternative management systems and new cultural practices that have minimal adverse impacts on the water supply while maintaining water use efficiency.

- Impact which the leaching of basic ions from soils has on soil productivity and the quality of irrigation water and watersheds.

- Procedures for determining effects of long-term exposure to chronic pollutants.

Augment Efficiency of Livestock and Poultry Production

Many commercial livestock and poultry producers are in serious financial difficulty. The keys to future profitability and stability for these and other producers include: accurately identifying producer needs, assembling the resources required to address these needs, and orchestrating programs which effectively solve problems. The year round production and care of slaughter and dairy animals and poultry can benefit from further research and extension efforts on key components of animal production systems.

In spite of the importance of livestock products to the consumer and the importance of livestock enterprises to American agriculture, numerous problems limit further improvements in production efficiency of animal agriculture. Many of these problems can be solved only by the creation of new technology or by more widespread adoption of existing technology.

Reproductive inefficiency has consistently been identified as one of the most costly and production-limiting problems facing the animal industries. Although significant progress has been made in our understanding of the reproduction phenomenon, improvements in reproductive efficiency have been slow.

The forage-ruminant complex is one of the major food-production systems of this and many other countries. A highly efficient and economic system for the conversion of solar energy (via plants) to human food depends on improved management systems for forage production and utilization by ruminant livestock.

Additional research attention should be directed to:

- Cellular and molecular processes regulating protein synthesis and fat metabolism.

- The absorption, assimilation, and utilization of nutrients.

- Physiological and endocrinological factors associated with high reproductive efficiency.

- Genetic and physiological relationships among traits.

Education efforts should be expanded to:

- Encourage the use of a systems approach to improve reproduction, nutrition, housing, health, management, marketing, and financial practices while improving quality of products and increasing net income.

- Develop and make available models that forecast for specific livestock and poultry systems the results of various inputs in terms of yield, income, and capital requirements.

Improve Management of Animal Diseases and Pests

Diseases of food animals are important causes of reduced production efficiency. Livestock and poultry producers face major and unpredictable risks of substantial losses from diseases, parasites, and other health hazards. In the United States, 15 to 20 percent of food animals die before reaching market. Some exotic infections, such as African swine fever, viscerotropic, velogenic Newcastle disease, and foot-and-mouth disease are serious threats to the U.S. livestock industries. Most highly contagious epidemic diseases have been controlled. Production diseases, many of which present no recognizable clinical signs, are the most important contributors to reduced productivity. These losses, plus the inefficiencies caused and the treatment costs for animals that recover from illness, are equal to an estimated 25 percent of the annual cash income for livestock and poultry.

Market competition and modern production practices, including high costs for labor, investment, and facilities, have required that large numbers of animals be kept closely confined. Despite the many health advantages to this practice (health surveillance; protection from parasites, predators, and climatic extremes; and accessibility for better health care) the spread of certain diseases is enhanced by the proximity of animals in a group. Because of public concern, the use of some medicants available for controlling animal health hazards is threatened. New or altered technology must be developed to combat new diseases or to replace measures no longer permitted or no longer effective. The use of recombinant DNA technology to produce vaccines and other biological materials at reasonable cost is encouraging.

Increased research effort is needed to:

- Characterize interactions between stress and disease.

- Study nonchemical control of pests and disease vectors.

- Develop vaccines and diagnostic tests through immunogenetic and bioengineering techniques.

Additional extension emphases are necessary to:

- Acquaint producers with housing and management techniques necessary to reduce losses from pests and diseases.

Increase Aquatic Food Production

Aquatic food production, an old idea that has found a new emphasis, is an expanding enterprise with considerable economic potential. It affords opportunity to help keep prime lands and waters in production, meet increased demand for fish, reduce dependence on imported and wild fish products, increase rural employment and farm income, and increase availability of high-quality fish products.

An interdisciplinary research approach is needed to:

- Develop efficient and profitable production management systems.
- Improve food-product quality.
- Improve food-processing procedures.
- Enhance new food-product development.
- Alleviate transportation and marketing problems.

Extension efforts are needed to:

- Improve rapid transfer and adoption of research-based technology to solve major nutrition, health, pest, and financial problems.
- Improve financial and risk-management expertise of growers, processors, and marketers.
- Assist in orderly development of expanded marketing opportunities through electronic data base management.

Improve Food Quality and Safety

A complex but effective interaction of the private and public sectors in research, education, regulation, and management contributes to the quality and safety of our food supply. Research and education efforts to improve quality and safety provide important linkages between production of high-grade, wholesome agricultural products on one hand and consumption and human nutrition on the other. Constant vigilance and testing are required throughout the marketing channels to assure that quality is maintained and foods are safe.

The safety and quality of our food supply is so consistent that it is often taken for granted. But new problems keep emerging and there is still much basic knowledge and application needed to continue to improve food quality and safety. Continued research and education are needed about the chemical, physiological, and molecular processes and properties of agricultural products, developing and utilizing new processing and handling

technologies, quality evaluation procedures, reduction of nutrient losses, and determination of new quality and safety standards and procedures.

More emphasis is needed on:

- Developing improved technology to prevent, detect, and remove natural and environmental toxins and pathogens from food products.
- Devising more efficient and safe food processing and handling methods.
- Improving the nutritional quality and nutrient bioavailability of food products through production and processing approaches.
- Ascertaining the safety of new food products and processes.
- Developing new chemical, mechanical, or electronic methods for more objective evaluation of quality and acceptability.
- Assuring that food products contribute to nutritional well-being.

Improve Family Financial Management

American families are called on to make increasingly complex financial and resource management decisions. Family financial problems compound when net farm incomes go down and financial stress increases. Deregulation of financial and consumer services has not only expanded the choices but also increased the decisionmaking responsibilities and hazards of families. People need accurate information and improved skills to assure family economic stability in planning and implementing for both short- and long-range goals.

Family financial management focuses on the acquisition, allocation, and conservation of personal and family incomes and on the household's ability to plan and use resources to achieve financial goals and maintain a desired level of living. It includes decisions concerning employment, education, food purchases, energy conservation, housing choices, credit uses, retirement, and estate planning. To make informed decisions in these areas, families need to understand how their needs and goals change over time and how to interpret economic, financial, and market trends that influence their choices.

The goal of family financial management assistance is to provide accurate, timely, and useful information and to develop family financial skills that will:

- Improve understanding of the long-run consequences and interrelations of financial decisions made early in life.
- Help consumers understand and assess financial risks inherent in both new and established financial services and instruments.

- Help families enhance their income-earning capabilities by developing home-based businesses and by marketing the skills of family members.

- Improve capacity of families to manage food, housing, household, clothing, energy, and credit costs, thereby increasing family stability and security.

Encourage Home Horticulture

Gardening traditionally has been an integral part of most farm operations. Farm families grow fruits and vegetables primarily to improve their diet and nutrition, but gardening also can provide an income supplement, job opportunities for family members, recreation, and therapeutic benefits. Home canning and freezing of horticultural crops extend the enjoyment and nutritional benefits of home-produced fruits and vegetables throughout the year.

Urban areas have many vacant spaces that can become eyesores, encourage vandalism, contribute to unchecked weed growth, and create health hazards. At the same time, many people with low incomes and poor nutrition gravitate to the cities. The urban gardening program was developed to help those people with the greatest need produce vegetables to supplement their diets and incomes on land donated for this public use. In many cases, urban gardening is the first exposure of urban youth to the concept of where food comes from.

The migration of urban residents to the suburbs has produced a new generation of gardeners who are eager but unskilled. They have added an unprecedented increase to the Extension workload in suburban areas. New technology and new methods, such as master gardeners, horticulture hotlines, taped messages, and similar approaches provide assistance on a more cost-effective basis.

Home horticulture programs can:

- Improve diets and supplement incomes while providing recreation and job opportunities for family members.

- Transform blighted urban areas and encourage community pride by using those areas for food production and recreation.

- Encourage young and adult gardeners to appreciate natural resources, accept responsibility, develop personal satisfaction, and create pride in their neighborhood.

- Expand the core of volunteer master gardeners that will enable Extension to provide better service to clientele who are interested in growing gardens, lawns, and shrubs.

Improve Agricultural Policy Analysis

American agriculture has changed. Large commercial farms dominate U.S. farm production. The operators of the remaining smaller farms generally are not poor and do not depend solely on farm income. Many of the commercial farms can be competitive in world markets, but may be hindered by present policies. The smaller farms do not benefit much from traditional commodity programs. These factors have changed the public's perception about agriculture and raised questions about the objectives of farm programs and who benefits from them.

At prices near or above recent support levels, demand for U.S. agricultural products is unlikely to be strong through the decade of the 1980's. There is also growing awareness of the importance of price in world markets. How the Nation chooses to reconcile this issue (the objective of maintaining farm income on the one hand and expanding exports on the other) is critical to the character of U.S. agriculture in the rest of the century. These choices will determine not only price levels and how they are set, but also who will produce and where.

Domestic farm policy tends to drive agricultural trade policies. Further, domestic farm policy is becoming more closely linked to resource and environmental policies. Agricultural programs may influence the long-term use, availability, and productivity of soil and water resources. Production inputs may affect the safety of products and influence the quality of resources for those who use them directly. Agricultural production is influenced by industrial pollution, such as acid rain. Thus, lawmakers are becoming sensitive to these multiple interests and their implications, and to the linkages between various domestic policy tools.

Research programs are needed to:

- Evaluate emerging policy issues in the broadest possible context. Agricultural policy is no longer in a separate arena. Information is needed on the impacts of alternative policy options on producers, consumers, soil and water resources, foreign trade, and the environment.

Extension programs are needed to:

- Inform producers and the general public on policy implications in order to stimulate informed citizen involvement in the public policy process.
- Provide information to the public in order to enable individuals and businesses to make practical business decisions in view of policy changes.

Improve Economic Information on U.S. Agricultural Trade

Although today the United States is competitive in world markets for most of its agricultural and forestry exports, its future competitive position and comparative advantage are in question. Comparative advantage is a dynamic concept. It is affected by national policies and by investments in human resources, research and development, natural resources, and marketing and transportation. From a domestic perspective, the issue concerns the ability and willingness of the United States to make appropriate investments to maintain and enhance the competitiveness of its agricultural products in world markets. A related issue concerns the ability of the United States to be competitive in exporting value-added agricultural and wood products.

Many countries protect their agricultural producers from price variability in international commodity markets. Agricultural price and income support programs often result in supply conditions that cause the imposition of import barriers, export subsidies, production controls, stocking programs, or some combination of these to balance quantities produced with quantities used and influence agricultural trade patterns. These policies cause more variable world market prices for agricultural products. As a result, U.S. producers with big stakes in export outlets face highly variable market conditions.

Agricultural trade patterns are influenced by import barriers, export subsidies, production controls, stocks management, and related trade policies. To what extent do these policies restrict the pursuit of comparative advantage? What U.S. trade strategies will minimize the effect of the trade policies of other countries? Will a domestic stocks policy provide a sufficient buffer against shocks in trade patterns? Which sector of the economy, and who among the trading partners, should bear the costs of programs to promote trade stability?

Two important issues result from policy-induced world price variability: (1) how and by whom shall costs of adjusting to instability be borne? and (2) what measures will be most effective in moderating the fluctuations in agricultural prices and supplies? The United States may need new or altered policies and programs to deal with international trade problems. Stocks management will be an important component of policies to deal with instability. These and other issues must be addressed in the context of domestic commodity and trade policies as well.

Research programs are needed to:

- Monitor changes in the global conditions that give rise to price variability—such as weather, domestic policies, world stock levels, trade barriers, and trade agreements—and improve the forecasting of developments in world agricultural supply, demand, and trade.

- Improve and extend foreign country data and information on the technical, economic, and institutional variables that affect costs of production, comparative advantage, and competitiveness. These data will permit improved long-range projections of world supply and trade of agricultural and forestry commodities.

- Increase the potential for the production and export of higher valued agricultural and forestry products.

Extension programs are needed to:

- Improve producers' knowledge about the international markets for their commodities, including the availability of monitoring and outlook information on world production and prices, so they can improve the timing of their marketing activities.

Expand Domestic and International Markets for Agriculture and Forest Products

Market expansion is vital to the welfare and prosperity of American farmers and to the U.S. economy. Growing markets maintain national employment, restrain inflation, and improve our balance of payments. The growth of American food, fiber, and forestry industries depends on their ability to sustain improvements in productivity, efficiency, and product quality and increase output in line with demand. Lagging productivity and efficiency contribute to higher prices for agricultural products, declining markets, and a loss of U.S. jobs. Labor-intensive production and processing are shifting to other countries with lower wage rates. Market development needs to focus on new products and new uses for agricultural products. Consumer attitudes and preferences, both domestic and foreign, affecting the consumption of farm products need to be explored and satisfied to expand demand.

Foreign trade in agricultural and forestry products expanded greatly during the 1970's. Spurred by favorable prices and growing demand, American farmers increased their investment in production facilities to take advantage of this market opportunity. Production from one out of every three U.S. acres now goes to foreign markets. During the last 15 years, the surplus from agricultural trade has provided foreign exchange to help pay for imports of petroleum, other raw materials, and consumer goods. It also has contributed to U.S. world political and economic leadership, sustained incomes and employment in agriculture and related industries, and held down costs for farm price and income supports.

Agricultural exports have dropped more than 20 percent since 1981, partly because of the high value of the dollar in foreign trade. Financial problems and improved food production in many countries—particularly developing countries—contributed to the decline. The decrease in farm exports has reduced farm incomes, increased the cost of government price and income support programs, revived trade conflicts, and renewed a shift toward protectionism.

To expand domestic and foreign markets for the U.S. farm products, research and education programs are needed to:

- Improve the efficiency and competitiveness of producing, processing, and distributing agricultural and forest products.

- Improve post-harvest handling, processing techniques, product development, and marketing strategies that will lead to more value-added products and increased market penetration.
- Develop new uses, new processes, and new products that are more acceptable to domestic and foreign consumers.
- Improve the understanding of the effects of international economics, alternative trade policies, trade barriers, monetary policy, exchange rates, and world supply and demand on international trade and their impact on private and public decisions on trade policy.
- Improve the development and coordination of research and information systems to link production and marketing more closely with consumer demands and marketing requirements.
- Encourage the continuing efforts of government agencies, universities, and the private sector in promoting economic development in developing countries to expand the future market potential for U.S. agricultural products.

Increase Public Education on Agriculture

The largely urban U.S. society has little appreciation for the difficulties involved in a biological food and fiber production system dependent on weather, diseases, insects, and other natural variables. Nor are citizens concerned about whether the financial, business, and regulatory environment will result in an efficient, progressive, and productive agricultural sector. The public has a low level of understanding and support for the changing economic, institutional, and political settings for the production and marketing of agricultural products here and abroad.

The U.S. food and fiber system is under substantial pressure to adjust to changing national and international conditions. Those who serve agriculture in private business and public positions live and work in an increasingly complex system of laws and regulations. Further complicating the area of agricultural policy is increasing intrusion from other sectors on regulatory issues such as environmental quality, employee safety, trade practices, and food labeling.

U.S. citizens need a better understanding of agriculture and its related industries and of the consequences of alternative agricultural policies so they can participate more effectively in setting those policies. The agricultural science and education system must develop and implement an agricultural policy education program that will:

- Bring about an awareness that agriculture is our most basic and important industry.
- Increase citizen understanding of the interrelation and interdependence of farmers, industry, and government in bringing high-quality, low-cost food, fiber, and forest products to consumers.

- Generate public understanding and support for the role of food and agriculture in the U.S. society and economy.

- Raise the awareness of impacts of international trade on agriculture and our domestic economy.

- Disseminate useful and timely information on challenging issues of public concern such as water pollution, pesticide use, agricultural waste disposal, groundwater quality, and food quality and safety.

Develop Volunteer Leadership

The effectiveness and efficiency of the Extension education system are enhanced by the time, effort, enthusiasm, skills, talents, and commitment of local volunteers. Volunteers continue to make educational programs highly cost-effective by their leadership and assistance in identifying needs, teaching and sharing information, extending program capabilities and resources, and working with local organizations and community projects. Through proper recruiting, training, and utilization of volunteers, Extension can, in part, offset declining public investment while continuing to maintain or expand program benefits.

A recent national study on the Implications of Volunteerism in Extension showed that in 1983 some 2.9 million volunteers spent more than 71 million days helping 48.7 million people in their communities. Volunteers invested 51 days of service for each day spent by an Extension agent in support of volunteers. If communities had paid for volunteers' services, the bill would have been more than $4.5 billion—five times greater than the total budget for the Cooperative Extension Service. A 10 percent improvement in volunteer management efficiency could contribute a $450 million increase in services to Extension clientele.

The science and education community must continue volunteer management and development programs that recruit, train, assist, and utilize volunteers in advising, planning, implementing, and evaluating programs. Special emphasis is needed to:

- Increase volunteer participation in master teacher and middle management roles and expand overall program participation.

- Initiate and expand representation and services to limited resource and hard-to-reach clientele and expand efforts to secure greater participation of these groups as volunteers.

- Teach volunteers skills that enhance their employability.

- Expand use of volunteers so that professionals can focus more time on training and on managing educational programs.

Expand Use of Electronic Communications/ Computer Systems

New knowledge and technological developments in the food and agricultural sciences are not utilized quickly enough for maximum effectiveness. Most individual information users do not have the ability to use computers and other new communication technologies. Yet, they must integrate information, knowledge, and techniques from the numerous disciplines into cohesive, flexible, and economical operating systems. Extension professionals and volunteers are not trained to use electronic communications systems effectively with youth and adults to improve the rate of technology transfer, obtain information, and make priority decisions related to agriculture.

It is important to accelerate the use of this rapidly advancing field of communications technology, so that all conveyors and users of food and agriculture information will benefit from the use of rapid, modern information delivery systems.

Research is needed to:

- Develop, test, and implement computerized decision-aid models to assist in knowledge integration.
- Develop an easily accessible, electronic, informational resource to speed the transfer of knowledge and increase the rate of adoption of new technology.
- Explore the use of other communication technologies such as interactive teleconferencing and satellite delivery to expand program delivery capacity.

Extension programs are needed to:

- Equip and train extension personnel to utilize communication technologies and computer systems and integrate them into their educational programs.
- Provide a software development and evaluation system to ensure that accurate, reliable, and useful educational and decisionmaking aids will be available.
- Expand programs on computers, networks, and other new communications technologies for improved decisionmaking.
- Develop informational data bases and make them available through public and private-sector networks to serve as up-to-date, state-of-the-art information resources.

Agricultural
Research Service

The Mission of the Agricultural Research Service

FOREWORD

This document states the mission of the Agricultural Research Service (ARS) of the U.S. Department of Agriculture (USDA). It also describes the specific scientific activities through which ARS pursues that mission in three contexts.

As one component in the full U.S. agricultural research and development system, ARS carries out research that is critical for maintaining the vitality and productivity of the Nation's food and agricultural industries. There is valid consensus that the current strength and well-being of those industries have resulted from, and will continue to rely on, effective research.

As the research arm of the USDA, ARS responds to the needs of the vast complex of interactive industries that produce, process, and deliver agricultural products to consumers in the United States and around the world. The activities of ARS mirror that complex but are assembled in the agency in a way that efficiently supports the diverse and separate phases of agriculture.

As a Federal system of science laboratories, ARS provides an extensive network of research centers, locations, and work sites. They are strategically located in the geographic areas best suited for the pursuit of research on specific agricultural commodities and on specific problems. Many are near Land-Grant Universities and State experiment stations with whom ARS cooperates. In the ARS organization, research activities are decentralized, but they are centrally managed.

This document highlights some of the special capabilities that ARS has developed to meet the specific needs of agriculture and to solve its specific problems. The many statutes legislated since 1862 that have shaped ARS and to which ARS must respond are summarized in Appendix A.

The Agricultural Research Service, its programs, and its employees reflect the dynamic nature of the complex that is U.S. agriculture. The enviable record of U.S. agriculture is a tribute to the generations of scientists who have contributed to every area of research included in their mission. Specific objectives in that mission have changed during the last 20 years and will continue to change. Overall, however, the sole mission of ARS, the world's largest and most diverse national research organization, is research that responds promptly to the changing needs of U.S. agriculture.

Issued July 1982
Slightly revised January 1983

More specifically, ARS conducts research that is--

1. National in perspective in that it focuses on significant problems affecting the entire Nation or its several broad geographic areas;

2. Sufficiently long range, high risk, and of such broad scope as to require the unified planning, continuity of effort, and stable scientific environment maintained by the Federal research organization;

3. Not undertaken by other agricultural research institutions because of their narrower geographic focus or shorter term perspective; and

4. Uniquely a Federal responsibility in that it--

    a. Is requested by Congress or the Executive Branch and requires special skills, facilities, or capabilities of ARS;

    b. Requires a structure ready to respond to emergency situations of regional or national significance;

    c. Is international in nature, supporting foreign policy initiatives of the U.S. Government;

    d. Supports the development and maintenance of important national collections that are essential to scientific activities; or

    e. Supports Federal action programs.

SPECIAL CAPABILITIES OF THE AGRICULTURAL RESEARCH SERVICE

To accomplish its mission, ARS—

- Operates a complex organization that conducts research to achieve long-range objectives in agriculture, while ensuring dynamic, timely, and flexible responses to new problems and changing national goals;

- Maintains a network of research centers, locations, and worksites in the United States and abroad; and

- Encourages and nourishes a scientific environment that fosters the development of creative, innovative technical expertise.

The following are essential to the ARS mission:

A Centrally Organized Base of Scientific and Agricultural Expertise--The ARS national organization permits the quick formation and operation of multidisciplinary teams to respond to research needs. These teams are centrally coordinated and can be assigned to priority research or analysis of problems without conflicting demands on time or responsibility. The familiarity of ARS scientists with Government programs, action agency needs, and regional and national problems provides a unique overview perspective on the full agricultural research system.

Central Planning, Management, and Coordination--As a major component of the full research and development system, ARS centrally plans, coordinates, and manages diverse research programs that operate in a decentralized mode.

Unique Collections and Repositories--Unique collections and repositories of information and materials, developed and maintained by ARS, are essential in meeting national research needs and are heavily utilized by other public and private research organizations. They include the National Seed Storage Laboratory and other facilities for plant germplasm introduction and preservation; clonal repositories; disease-free seed stock; the ARS Culture Collection; and other taxonomic collections of plants, microbes, and insects.

Critical Mass of Scientific Talent--The diversity of its scientific work force allows ARS to assign critical masses of scientific talent to geographically broad problems not readily undertaken by State, private, or industrial institutions. Research teams can be established from ARS' own scientific resources and used in coordination with resources of the State agricultural experiment stations and other institutions. These teams can attain the critical mass that is vital to the interaction and stimulation needed for scientists to generate new ideas and resolve complex problems.

Extensive Resources Specific to Research in Agriculture--Much of ARS resources of expertise and facilities complements and supports other parts of the full agricultural research system. Its regional research centers are invaluable national resources; they are recognized internationally as premier agricultural research establishments. ARS has specialized facilities for research on exotic diseases of animals and plants and on the insect vectors of such diseases. It also has resources for implementing long-term, high-cost, high-risk research in facilities that other research organizations cannot establish or maintain. The reservoir of information and experience at ARS research centers is highly important to the continuity and progress of the full U.S. agricultural research and development system. In addition, ARS has the capability to develop scientists through its Office of Higher Education.

ORGANIZATION AND OPERATION OF THE AGRICULTURAL RESEARCH SERVICE

ARS is centrally managed by the Administrator, who is located at the USDA Headquarters in Washington, D.C. He is assisted in planning, budgeting, and managing the overall ARS program by the ARS National Program Staff (NPS), which is led by the Deputy Administrator. The Deputy Administrator is located at the Beltsville, Maryland, Agricultural Research Center. General performance of research is managed through four Regional Administrators who are responsible for activities in each of the four geographic regions shown in Appendix C. These regions roughly correspond to the four State agricultural experiment station regions. Each region operates under standard hierarchical management, and certain responsibilities are delegated to Area and Center Directors. Certain cross-cutting activities may be assigned to mid-level project managers.

Administrator

The Administrator is responsible for all ARS activities, including planning, executing and balancing programs, and deploying resources to achieve the objectives of the Agency. He formulates ARS policy and advises the Department on policy relating to national agricultural research matters. He has overall responsibility for coordinating ARS' planned activities with cooperators in the public and private sectors and with other Federal agencies served by ARS. He is responsible for assessing general program progress and evaluating broad program areas for performance in attainment of stated goals and objectives. He also represents ARS to the Assistant Secretary for Science and Education, the Secretary of Agriculture, and other such Cabinet- and sub-Cabinet-level Administrators with whom ARS interacts.

Deputy Administrator, National Program Staff

The Deputy Administrator serves as the leader of the NPS. He and his staff are the Administrator's chief technical advisers for national research programs and are responsible for the technical excellence of the national research programs. He and his staff have direct responsibility for leading budget development, coordination, review, and evaluation of ARS national programs to ensure proper interaction, balance, and distribution of research efforts focused upon national and major regional issues.

The Deputy Administrator and the NPS are responsible for--

- Providing national technical leadership of ARS programs;
- Establishing long-range goals, strategic and operational plans, and program priorities;
- Planning and conducting program reviews;

- Coordinating, monitoring, and evaluating national and regional programs;

- Maintaining coordination with scientists, administrators, and public and private cooperators on research and budget needs; and

- Providing liaison for ARS programs between ARS and the Federal, State, private, and public interactors with the ARS system.

Regional Administrators

ARS Regional Administrators are responsible for laboratory and field implementation of ARS' programs in their respective Regions in accordance with the Administrator's policies and the stated goals and objectives of the ARS Strategic Plan. They are responsible for implementing that part of the national operational plan that falls within their respective Regions and for ensuring that such implementations are in full agreement with the national plan. Regional Administrators, with the Deputy Administrator and NPS, provide counsel to the Administrator on policy issues and budget development. Regional Administrators serve as line managers for ARS program implementation through a hierarchy of Area and Center Directors and of Research Leaders at individual locations. They are responsible for program performance and resource management at the regional level.

The Regional Administrators and their Area and Center Directors--

- Direct and execute approved programs;

- Recruit, employ, evaluate, and make the best utilization of ARS scientists in keeping with national program needs and requirements;

- Participate with NPS in planning and conducting program reviews and in executing recommendations resulting from them;

- Approve annual reports and plans, as well as position resource management plans;

- Participate with NPS, through the ARS Budget Board, in developing the ARS budget; and

- Maintain coordination with State experiment station directors, regional councils, and other individuals and groups that have an interest in agriculture.

ARS FACILITIES

The ARS facilities for agricultural research are extremely diverse and unequaled throughout the world. Research is conducted at many centers, laboratories, and locations that range in size from small stations to the large 450-scientist facility at the Beltsville, Maryland, Agricultural Research Center.

Most facilities are owned and operated by ARS, but several locations are provided by the U.S. General Services Administration or are leased. Some locations are designed to address research problems that have a very specific focus. Other facilities, such as the Beltsville Agricultural Research Center, have a wide array of programs that are best addressed by a multidisciplinary approach and require equipment and facilities for many scientific disciplines and activities. ARS facilities are located throughout the United States and overseas so that problems of regional, national, and international nature can be addressed under the most favorable research environment. Many are located on university campuses and State agricultural experiment stations to assure cooperation and interaction with State scientists.

This type of arrangement encourages joint use of expensive research equipment, as well as of other essential facilities such as libraries, computers, and experimental plots. The following is a descriptive listing of ARS facilities grouped according to the following areas of agricultural research activity: Major National and Regional Centers; Human Nutrition Research Centers; Crop Sciences Facilities; Livestock and Veterinary Sciences Facilities; Postharvest Science and Technology Facilities; and Soil, Water, and Air Sciences Facilities.

Major National and Regional Centers

Beltsville Agricultural Research Center (BARC)--With more than 450 full-time scientists, BARC is the largest center of excellence for national agricultural research in the United States and, possibly, the world. More than 7,000 acres of land are intensively utilized for plant and animal research. The hundreds of buildings meet the many specialized needs of the research program and house highly specialized equipment such as the computerized calorimeter in the Energy Metabolism Laboratory. The National Agricultural Library, located on the Center's grounds, is an important resource for all scientists. The close proximity of BARC to the Nation's Capital, headquarters for many Government agencies that include action and regulatory agencies and numerous research institutions associated with agriculture, is unique. The Center provides a panorama of agricultural research for visitors from many agencies and from many nations.

BARC has many interdisciplinary research teams of scientists with expertise in all agricultural disciplines and nearly all commodities. The Center is in a unique position to assemble scientific resources to attack specific problems of national importance. In addition, BARC houses major national taxonomic collections of insects, fungi, seeds, nematodes, animal parasites, and rhizobia. These collections and their evaluations provide essential national services for other scientists, for industry, and for regulatory agencies. The Center is located in Beltsville, Md.

Regional Research Centers and the Richard B. Russell Agricultural Research Center--The four regional research centers, together with the Richard B. Russell Agricultural Research Center, comprise a resource unmatched throughout the world. Each center represents a unique concentration of scientists with specialized scientific knowledge and of highly specialized instrumentation and equipment essential to conducting the basic and applied research needed to solve complex agricultural problems. Nearly 600 scientists are located at these five centers.

Each center has the scientific and engineering expertise necessary to respond to emergency needs of national or regional importance and to provide the continuity of effort required to conduct long-term basic research. The centers are especially capable of dealing with problems associated with postharvest technologies critical to the delivery of high-quality, nutritious, and safe food and fiber to consumers. Thus, the centers bridge the gaps among the interests of agriculture, industry, and consumers. The facilities are the Eastern Regional Research Center, Wyndmoor, Pa.; Northern Regional Research Center, Peoria, Ill.; Southern Regional Research Center, New Orleans, La.; Western Regional Research Center, Albany, Calif.; and Richard B. Russell Agricultural Research Center, Athens, Ga.

National Arboretum--The U.S. National Arboretum, established by an Act of Congress on May 4, 1927, comprises 444 acres in Washington, D.C. The Arboretum is a research institution for trees and other ornamental plants. Its work includes the improvement of plants through introduction, breeding, and selection. In 1973 the Arboretum was placed on the National Register of Historic Places.

The Arboretum has a major herbarium containing 500,000 botanical specimens for research and plant identification, and it publishes botanical findings and provides technical information to the public. In addition, it exchanges seed and plant material with other scientific institutions throughout the world to provide researchers with needed genetic resources and to enrich the educational collections displayed at the Arboretum.

Although not a park in the usual sense, the Arboretum provides ample opportunity for observing and enjoying plants. It has a steady flow of visitors--including scientists, landscape architects, gardeners, school children, and tourists--from around the world. As many as 20,000 people a day may visit the grounds and displays. The Arboretum is located in Washington, D.C.

Human Nutrition Research Centers

Human nutrition research is conducted at five research centers. Each has specific goals and objectives.

Beltsville Human Nutrition Research Center--The center at Beltsville, Md., plans and conducts research related to nutrient requirements for proteins, carbohydrates, lipids, vitamins, and minerals for optimal health and disease prevention. Research activities are associated with--

- Composition of foods containing the nutrients required by and biologically useful to humans; and
- Human requirements for proteins, carbohydrates, energy intake, lipids, minerals, and vitamins; and with the identification of the forms of these nutrients in various foods.

Grand Forks Human Nutrition Research Center--The center at Grand Forks, N. Dak., plans and conducts research related to human nutrient requirements, with emphasis on trace minerals. Research activities are associated with--

- Nutritional requirements for zinc, nickel, copper, and other minor elements and their relationships to optimal health, function, and performance;
- Physiological and biochemical factors that influence requirements for minor elements in all age groups; and
- Biological availability of minerals and the effects of nonnutritive factors in foods on availability of minerals.

Children's Nutrition Research Center at Baylor College of Medicine--The center, at Houston, Tex., plans and conducts research to develop a scientific basis for standards of nutrient intake and assessments of nutritional status. Research activities are associated with--

- Nutrient requirements in infants, children, and pregnant and lactating women;
- Relationships between nutrition and physical and mental development; and
- Role of diet in optimum growth and development.

Human Nutrition Research Center on Aging at Tufts University--The center at Boston, Mass., plans and conducts research on

nutrient needs of the elderly and the relation of dietary factors to the aging process. Research activities are associated with--

- Nutritional needs for optimal health, function, and performance throughout life; and

- Nutritional requirements in the aging population.

Western Human Nutrition Research Center--The center at San Francisco, Calif., plans and conducts research related to intervention programs and nutritional requirements. Research activities are associated with--

- Factors resulting in suboptimal nutritional status;

- Reliable, efficient, and inexpensive methods for defining nutritional status;

- Human nutritional requirements; and

- Nutritional criteria for designing and evaluating intervention programs.

Crop Sciences Facilities

Aquatic Weed Research Laboratories--Multidisciplinary teams that include weed scientists, plant physiologists, biochemists, chemists, soil scientists, entomologists, plant pathologists, ecologists, marine biologists, and others cooperate to develop ecological, mechanical, biological, chemical, and integrated management systems for the control of aquatic weeds in irrigation systems, drainage canals, water reservoirs, farm ponds, and other aquatic sites. Greenhouses, controlled-growth phytotrons, experimental ponds, model irrigation systems, and quarantine and other unique facilities are available for evaluating fish, insects, plant pathogens, snails, mammals, other biological organisms, selective chemicals, and water management as means of controlling aquatic weeds. Cooperating with ARS in these efforts are other Federal agencies, State agricultural experiment stations, and industrial organizations that generally do not maintain research staffs and facilities for research on aquatic weeds. The facilities are located at the Aquatic Weed Control Research Laboratory, Fort Lauderdale, Fla.; Southern Weed Science Laboratory, Stoneville, Miss.; Weed Control Research Laboratory, Prosser, Wash.; and Aquatic Weeds Control Research Laboratory, Davis, Calif.

Barley and Malting Quality Laboratory--This laboratory, which has unique facilities for determining malting quality, serves Federal and State research programs in the North Central, Mississippi Valley, and western barley-growing regions. Specialized facilities for studying the biochemistry of malting are provided to serve these projects, as well as to investigate basic processes involved in malting. The laboratory is located in Madison, Wis.

Bee Research Laboratories--In these ARS laboratories, a critical mass of scientists with special expertise work on pollination problems of importance to the whole country. These facilities are equipped with specialized support buildings and cages. For example, isolation is required so that large numbers of normal and specialized bee colonies can be maintained near the laboratories. Facilities are located at the Honey Bee Pesticides and Disease Research Laboratory, Laramie, Wyo.; Bee Breeding and Stock Center, Baton Rouge, La.; Carl Hayden Bee Research Center, Tucson, Ariz.; Wild Bee Biology and Systematics Research Laboratory, Logan, Utah; Bioenvironmental Bee Laboratory, Beltsville, Md.; and Bee Management Laboratory, Madison, Wis.

Biological Control Research and Quarantine Facilities--These laboratories house specialists experienced in foreign and domestic field or laboratory studies of exotic beneficial organisms that may be used to control pest insects, pathogens, and weeds. The concentration of expertise in a few, highly secure quarantine facilities where research can be done safely produces an excellent environment for conducting fundamental and applied research. These facilities are used by State departments of agriculture, State agricultural experiment

stations, USDA's Animal and Plant Health Inspection Service, USDA's Forest Service, and other organizations that wish to actually release organisms in the field. Facilities are located at the Plant Disease Research Laboratory, Frederick, Md.; Delta States Research Center, Stoneville, Miss.; Beneficial Insects Research Laboratory, Newark, Del.; Biological Control of Weeds Laboratory, Albany, Calif.; Biological Control of Insects Research Unit, Columbia, Mo.; Biological Control of Insects Laboratory, Tuscon, Ariz.; Biological Control of Weeds Research Laboratory, Buenos Aires, Argentina; European Parasite Laboratory, Sevres, France; Biological Control of Weeds Laboratory, Rome, Italy; and Asian Parasite Laboratory, Seoul, Korea.

Cereal Disease Laboratories--These two laboratories have specialized facilities for investigating the behavior of major cereal diseases of national scope. The laboratories maintain national oversight of the epidemiology of major cereal diseases, conduct and maintain national surveys of disease races, and investigate the basic genetics of disease resistance. The facilities are located at the Cereal Rust Laboratory, St. Paul, Minn., and the Corn Virus Research Laboratory, Mississippi State, Miss.

Cotton Research Laboratories--These four laboratories are located in production regions that differ in soil type, climate, water management, and pests. At each location, teams of 9 to 16 geneticists, agronomists, physiologists, and plant-protection scientists work together to develop improved cotton production systems. Facilities are located at the ARS Western Cotton Research Laboratory, Phoenix, Ariz.; U.S. Cotton Research Station, Shafter, Calif.; Cotton Insects Research Laboratory, Brownsville, Tex.; and Cotton Research Laboratories, College Station, Tex.

Crop Commodity Insect Control Research Facilities--These facilities provide locations where a critical mass of scientists--entomologists, plant breeders, geneticists, plant physiologists, chemists, engineers, and others--can cooperate in efforts to develop tactics, strategies, and systems that may reduce losses of major commodities to insect pests. These concentrations of personnel permit the effective use of rearing facilities, greenhouses, and specialized equipment. In addition, they facilitate the interdisciplinary research required to solve complex pest-management problems of national importance. Facilities are located at the Cotton Insects Physiology Research Unit, Baton Rouge, La.; Cotton Insects Research Laboratory, Brownsville, Tex.; Southern Grain Insects Research Laboratory, Tifton, Ga.; Northern Grain Insects Research Laboratory, Brookings, S. Dak.; Citrus Insects Research Laboratory, Weslaco, Tex.; Fruit and Vegetable Insects Research Laboratory, Vincennes, Ind.; Yakima Agricultural

Research Laboratory, Yakima, Wash.; Subtropical Horticultural Research Station, Miami, Fla.; Boll Weevil Research Laboratory, Mississippi State, Miss.; Boll Weevil Eradication Research Laboratory, Raleigh, N.C.; and Boyden Entomology Laboratory, Riverside, Calif.

Crops Research Laboratories--These two laboratories are located in production regions that differ in soil type, climate, water management, and pests. The research is conducted on sugarbeets, forage, and range and is aimed at breeding and production practices and pest control. Multidisciplinary teams of 10 to 12 scientists include plant breeders, geneticists, agronomists, plant pathologists, physiologists, and nematologists. In addition to office-laboratory space, the facilities include greenhouses with growth chambers, temperature- and humidity-controlled chambers for sugarbeet storage, and special isolation chambers for pollination. Facilities are located in Ft. Collins, Colo., and Logan, Utah.

Forage-Range-Livestock Research Stations--These five ARS stations are located in different production regions. Soil type, plant and animal species, climate, and other environmental factors interact to create unique agricultural production situations of national importance. At each location, teams of 4 to 10 scientists of many disciplines--breeders, geneticists, physiologists, agronomists, range and animal scientists, pathologists, and entomologists-- interact to solve problems and to increase production of forage and livestock from grasslands. These teams also work closely with scientists of other research agencies. Facilities are located at the U.S. Regional Pasture Research Laboratory, University Park, Pa.; North Central Dairy Forage Research Center, Madison, Wis.; U.S. Southern Great Plains Field Station, Woodward, Okla.; Squaw Butte Research Station, Burns, Oreg.; and Jornada Experimental Range Management Station, Las Cruces, N. Mex.

Fruit and Nut Crop Repositories--These repositories have been specifically located and maintained to provide vegetatively produced plant germplasm for U.S. scientists and are the first two of several planned. The Oregon repository maintains pome fruits, small fruits, filberts, hops, and mint. The California repository maintains stone fruits, grapes, walnuts, almonds, and certain minor crops. Involved are the collection, propagation, maintenance, and preliminary evaluation of such crops. These repositories are managed by curators and provide public, industry, and private breeders and other plant scientists with germplasm needed for crop improvement programs. They are distinct and separate from breeders' working collections. Facilities include office-laboratory space, screenhouses, greenhouses, isolation field plots, and temperature- and humidity-controlled storage chambers. The repositories are located in Corvallis, Oreg. and Davis, Calif.

Insect Attractants, Behavior, and Basic Biology Research Laboratory--The research at this laboratory is basic to management of insect pests of crops, stored products, and humans. The facility is unique because it is suitable for basic research on most processes of insect growth and development and of insect reception and response that are now believed to be the key to ecologically sound, selective, and safe methods of insect pest management. Unique instrumentation and skills have enabled the laboratory to solve problems for which solutions previously appeared to be difficult; for example, identifying and synthesizing attractants of serious insect pests. As a result, attractant pheromones for the Japanese beetle and for peach tree borers are now in commercial use. Behavioral and bioengineering research have yielded concepts and techniques that have been adopted to assure the quality of mass-reared sterile screwworms, Mediterranean fruit flies, and other insects. The use of pheromones and insect growth regulators to protect stored peanuts and other agricultural commodities has been developed to the pilot stage. The laboratory is located in Gainesville, Fla.

Mayaguez Institute of Tropical Agriculture--The mission of this institute is to aid continental U.S. agriculture by providing winter nurseries that permit year-round outdoor experimentation and development; to introduce, evaluate, select, multiply, preserve, and develop tropical crop germplasm of interest to U.S. agriculture; to aid the agriculture of Puerto Rico by conducting carefully selected cooperative studies; and to contribute to the development of agriculture in the tropics. The institute consists of one major building and 34 smaller support buildings on 207 acres of land adjacent to the University of Puerto Rico. In addition, a 125-acre farm, located about 25 miles north of Mayaguez at Isabela, consists mainly of experimental plots that include winter nursery operations. The institute provides an ideal location for a unique collection of subtropical and tropical plant germplasm. The institute is located in Mayaguez, P.R.

Metabolism and Radiation Research Laboratory--This national laboratory was established in 1964 to investigate the fate of pesticides, drugs, and other agricultural chemicals applied to crops, feeds, and livestock and to identify and explore insect vulnerabilities that can be exploited in managing insect pests. The laboratory has a highly trained interdisciplinary staff, unique equipment for irradiating insects, and an excellent collection of high-precision instruments for chemical analyses. The laboratory established, between wheat and wild oats, enzymatic differences that have been exploited by industry; established that diethylstilbestrol is stored in the livers of livestock; and discovered the first practical method of

sexually sterilizing boll weevils. The laboratory is located in Fargo, N. Dak.

National Seed Storage Laboratory--The National Seed Storage Laboratory, on the campus of Colorado State University, has been in operation since 1958. The mission of the laboratory is long-term preservation of valuable plant germplasm as viable seeds and research related thereto. Long-range studies focus on biochemical, physiological, and genetic changes in seeds during storage and the effects of seed moisture content, storage environment, and storage containers on seed longevity. Laboratory procedures for accurate monitoring of seed viability during storage are established on a crop-by-crop basis. Several million seeds, representing nearly 100,000 varieties, are stored in 11 cold-storage rooms. The laboratory is located in Ft. Collins, Colo.

Offshore Insect Control Research Facilities--ARS facilities in Hawaii and the Virgin Islands allow entomologists to conduct research and to produce experimental materials, such as sterile fruit flies, in isolated microcosms of mainland agricultural conditions. At the same time, the scientists can conduct research of direct benefit to these tropical and subtropical areas. These isolated locations form a unique national resource because they allow evaluation of procedures for managing pests that cause widespread damage to mainland crops and livestock. Facilities are located at the ARS Fruit Fly Laboratory, Honolulu, Hawaii; Hawaiian Agricultural Experiment Station, Hilo, Hawaii; and Federal Experiment Station, Kingshill, St. Croix, V.I.

Ornamental Plant Research Laboratory--This central laboratory was established to serve the needs of florists and nursery crop producers in the Pacific Northwest. The office-laboratory building is occupied by a multidisciplinary team of scientists consisting of plant pathologists, physiologists, an entomologist, an agronomist, and a soil scientist. The facility includes greenhouses, special isolation houses for pesticide research, and shade houses. Field work is conducted on nearby land leased from the State. The laboratory is located in Corvallis, Oreg.

Peanut Production, Disease, and Harvest Research Laboratory--This laboratory is located in the center of the Mid-Atlantic peanut production area. An interdisciplinary team of breeders, plant physiologists, and engineers work together to develop peanut production systems, applicable to the entire peanut production area, that will increase yield and improve product quality. The drying laboratory provides unique facilities for controlled studies of peanut drying. Work at this

facility is coordinated with work at other research institutions. The laboratory is located in Suffolk, Va.

U.S. Plant Introduction Station--This facility is the only USDA location for processing foreign plant germplasm that must be quarantined upon arrival in the United States. It is located in a nonagricultural area to ensure isolation of imported material, yet it is within a few miles of the Beltsville Agricultural Research Center and its available expertise.

Facilities include specially designed greenhouses and screenhouses for the maintenance of prohibited crop categories and foreign germplasm. Onsite expertise is available for performing indexing tests to detect a wide array of viruses, mycoplasmas, protozoa, spiroplasmas, and viroids. At the facilities are office-laboratory buildings that include 13 glasshouses, as well as cold rooms and specialized equipment. Plant varieties assembled on the grounds include 800 apple, 600 pear, 250 stone fruit, and 700 woody ornamental varieties. The station is located in Glenn Dale, Md.

Regional Plant Introduction Stations--These stations are located in the four geographic regions of the country for close cooperation with the State agricultural experiment stations. Each station is responsible for receiving, maintaining, increasing, distributing, and evaluating seeds of a specific array of crops and of potentially new crop species. These facilities are a key part of the national plant germplasm system, and they provide valuable national and international services to plant breeders, geneticists, and other scientists in the public and private sectors. Facilities are located in Experiment, Ga.; Ames, Iowa; Geneva, N.Y.; and Pullman, Wash.

Rice Research Laboratory--This laboratory is located on a State agricultural experiment station comprising nearly 1,000 acres. ARS scientists here study rice breeding, quality, diseases, drying after harvest, and storage insects. Onsite solar collectors and heat-storage units enable engineers to conduct pilot tests to improve rice drying with minimum energy inputs. The availability of more than 25 storage bins permits the study of rice-quality preservation over a period of several years. The ARS team effort encourages development of a quality-rice variety that will be resistant to plant diseases and postharvest insect attack. Because numerous commercial rice mills are located nearby, insect contamination of processed rice can be studied. The laboratory is located in Beaumont, Tex.

Subtropical Horticultural Research Station--This station is situated on 200 acres south of Miami. The staff consists of entomologists, plant pathologists, horticulturists, and an organic chemist. Research at the facility involves pest

control, reduction of marketing losses, and varietal and cultural improvement of subtropical plants. The station maintains unique germplasm collections of coffee, cacao, sugarcane, and other tropical and subtropical plants. The facility also provides for Federal and State cooperative programs on survey and detection of pests and on nursery inspection, postentry quarantine inspection, and development of coconut palms resistant to lethal yellowing disease. The station is located in Miami, Fla.

Sugarbeet and Vegetable Research Station--This facility serves the unique vegetable and sugarbeet production area of California's Salinas Valley and other production areas in the Western States. The valley opens to the ocean, making the location ideal for cool-season vegetables and sugarbeets. The facility includes an office-laboratory building, special greenhouses for isolation breeding, an electron microscope, a fully equipped agricultural engineering shop, and 100 acres of field plots. The station is located in Salinas, Calif.

Sugarcane Mechanization Laboratory--This facility provides shops and engineering laboratories that meet the space requirements for construction and testing of large field machines being developed for use in sugarcane production. The equipment developed at this facility is intended for use in both the Florida and Louisiana cane-production areas. Preliminary testing of new research concepts is conducted in ARS facilities, and field tests are conducted in State and privately owned fields. The laboratory is located in Belle Glade, Fla.

Sugarcane Research Laboratories--These two laboratories are located in sugar-production regions with different ecologies, soil types, water-management systems, diseases, insects, and cultural practices. Multidisciplinary teams include plant breeders, geneticists, agronomists, plant pathologists, plant physiologists, weed-control specialists, and entomologists. These locations have unique facilities, including large, tall, isolation-crossing houses with rail carts that move plants indoors at night, air-conditioned photoperiod houses, growth chambers, temperature- and humidity-controlled storage rooms, and sugarcane milling and harvesting equipment. Office-laboratory space is provided for 10 to 14 scientists. The facilities are located in Canal Point, Fla., and Houma, La.

Tree Fruit and Tree Nut Research Stations--Five regional research stations are located in production areas that differ in fruit-crop adaptation, soil type, climate, water management, and pests. Studies of tree fruit and tree nut crops differ by region and are conducted on citrus, apples, pears, peaches and other stone fruits, pecans, blueberries, and strawberries.

Teams of horticulturists, geneticists, pathologists, physiologists, entomologists, soil scientists, and agricultural engineers cooperate to develop new fruit and nut varieties and improved cultural systems. Scientific teams range from 4 to 18 scientists at the various locations. The research on perennial fruit crops is dedicated to long-range problems--research that is not easily initiated or justified by individual State agricultural experiment stations. The facilities are located at the Appalachian Fruit Research Station, Kearneysville, W. Va.; Production, Harvesting, and Handling of Tree Fruits, Wenatchee, Wash.; W. R. Poage Pecan Field Station, Brownwood, Tex.; Small Fruits Research Station, Poplarville, Miss.; Southeastern Fruit and Tree Nut Research Laboratory, Byron, Ga.; and U.S. Horticultural Research Laboratory, Orlando, Fla.

U.S. Delta States Agricultural Research Center--This research center emphasizes multidisciplinary, mission-oriented research in the basic and applied sciences, with the following objectives: Developing technology for improving crop production, harvesting, and processing efficiency; developing cost-effective technology for reducing crop losses caused by weeds, diseases, insects, and nematodes; improving environmental quality; and improving yields and quality of crops. Plant scientists, engineers, weed scientists, entomologists, plant pathologists, plant physiologists, chemists, nematologists, and soil scientists cooperate in contributing to these objectives.

Resources include controlled-growth phytotrons; greenhouses; research quarantine facilities for insects, plant pathogens, nematodes, and weeds; and large areas of land for field experiments. Research at the center is planned in cooperation with the States and industry to ensure emphasis on regional and national problems. The facility is located in Stoneville, Miss.

U.S. Vegetable Laboratory--This central facility was established as a regional laboratory to serve all of the Southeastern States for breeding, production, and protection of vegetable crops. It is located on 350 acres of prime vegetable cropland. It includes a large office and laboratory, a seed-storage building, special insect-rearing rooms, laboratories, vegetable-storage facilities, and several greenhouses. Scientists include geneticists, horticulturists, pathologists, agronomists, entomologists, nematologists, and a chemist. The Southeastern Forestry Research Laboratory is also located on the property, and a State substation occupies adjacent land. The facility is located in Charleston, S.C.

Livestock and Veterinary Sciences Facilities

Animal Disease Research Laboratories--The animal disease research efforts in ARS are concentrated at seven locations. One of these, the National Animal Disease Center in Ames, Iowa, is the largest such unit in the world and has a mission to conduct basic and applied research on diseases of national importance in cattle, sheep, swine, horses, and poultry The staff uses multidisciplinary approaches to solve animal health problems. The other animal disease laboratories are unique in that each specializes either in a single disease area or in specific diseases of a single animal species. The laboratories are located where a disease exists and where their scientists can readily collaborate with research scientists of other institutions. Chemists, virologists, bacteriologists, veterinarians, physiologists, entomologists, and pathologists work together on interdisciplinary approaches to disease control.

These ARS laboratories can conduct in-depth studies on economically important diseases that do not cause catastrophic losses and, therefore, often do not command continued support from State agencies or other Federal agencies. Because of their highly skilled staffs, the laboratories are excellent training locations for U.S. and foreign scientists who need specialized training. The large, interdisciplinary staffs also provide the United States with a highly trained research and diagnostic staff that can be mobilized rapidly to meet any animal disease emergency. Facilities are located at the National Animal Disease Center, Ames, Iowa; Arthropod-Borne Animal Disease Research Laboratory, Denver, Colo.; Animal Disease Research Unit, Pullman, Wash.; Southwestern Livestock and Forage Research Station, El Reno, Okla.; Regional Poultry Research Laboratory, East Lansing, Mich.; Southeast Poultry Research Laboratory, Athens, Ga.; and South Central Poultry Research Laboratory, Mississippi State, Miss.

Foreign Animal Disease Research Centers--ARS has unique responsibilities for research on animal diseases that do not exist in the United States but pose a continuous threat to U.S. livestock and poultry industries. The major portion of this research is conducted at the ARS laboratory on Plum Island, 1.5 miles off Long Island. One serious foreign disease being studied is foot-and-mouth disease which affects all farm animals except horses and poultry. By law the Plum Island laboratory is the only U.S. facility where this disease can be studied.

Another disease being studied extensively at the laboratory on Plum Island is African Swine Fever. No vaccine is available for this disease, which poses a serious threat to swine. Other foreign animal diseases that have been or are now being studied are rinderpest; contagious bovine pleuropneumonia; African

horsesickness; exotic strains of bluetongue; sheep pox; duck virus enteritis; Teschen disease of pigs; swine vesicular disease; and a serious blood-parasite disease called East Coast fever.

Under strict security regulations imposed by ARS and the Animal and Plant Health Inspection Service (APHIS), studies of fowl plague and exotic Newcastle disease are conducted by ARS at a laboratory in Athens, Ga. Another high-security facility for the study of insect-borne foreign diseases is located in Denver, Colo. A multidisciplinary team of veterinarians, microbiologists, immunologists, biochemists, electron microscopists, and pathologists develops research information that is essential in the diagnosis, prevention, control, and eradication of serious exotic diseases of animals that might gain entry into the United States. Facilities are located at the Plum Island Animal Disease Center, Greenport, N.Y.; Southeast Poultry Research Laboratory, Athens, Ga.; Arthropod-Borne Animal Disease Research Laboratory, Denver, Colo.; and Animal Disease Laboratory, Nairobi, Kenya.

Insects Affecting Livestock Laboratories--ARS research on insects affecting livestock is the largest single component of the U.S. effort to control insect pests. The work serves the livestock industry, which accounts for about half the cash income of American farmers. It also supports action programs of other agencies. For example, personnel are assisting in the screwworm eradication program being conducted by APHIS, in cooperation with Mexico, and plans have been made for future cooperative research with Canada's Agriculture Ministry to control the cattle grub. Other research is underway to support APHIS in efforts to control Texas cattle fever and cattle scabies.

The multidisciplinary teams of entomologists, chemists, immunologists, virologists, physiologists, and engineers at the several laboratories can be assembled and mobilized on short notice. They have the flexibility to conduct cooperative programs with APHIS, State agricultural experiment stations, and other governmental organizations on a regional, interregional, national, or international basis. Facilities are located at the Screwworm Research Laboratory, Mission, Tex.; Hemoparasite Disease Research Laboratory, Pullman Wash; Arthropod-Borne Animal Disease Research Laboratory, Denver, Colo.; Midwest Livestock Insects Research Laboratory, Lincoln, Nebr.; Livestock Insects Laboratory, Beltsville, Md.; Veterinary Toxicology and Entomology Research Laboratory, College Station, Tex.; Metabolism and Radiation Research Laboratory, Fargo, N. Dak.; Gulf Coast Mosquito Research Laboratory, Lake Charles, La.; U.S. Livestock Insects Laboratory, Kerrville, Tex.; Lone Star Tick Laboratory, Poteau, Okla.; Cattle Fever Tick Research Laboratory, Falcon Heights, Tex.; and Mayaguez Institute of Tropical Agriculture, Mayaguez, P.R.

Insects Affecting Man Laboratories--ARS research on insect pests of humans is the major such effort in the world. Most of the work is conducted in Gainesville, Fla., one of the largest and most specialized research facilities of its kind. Much of this work is conducted in support of the U.S. Department of Defense, which is concerned with preventing insect-borne diseases such as malaria, dengue, and encephalitis from reducing the efficiency of U.S. military personnel at home and abroad. In addition, personnel from the Gainesville laboratory serve as the technical nucleus for cooperative research with international organizations such as the United Nations and the U.S. Agency for International Development. A recent example of this type of cooperation was a project on the control of malaria-infectious mosquitoes in Central America.

The laboratory at Lake Charles, La., is strategically located for research on regional problems in support of APHIS programs. At both locations, the multidisciplinary teams of entomologists, epidemiologists, geneticists, and engineers can assist in instances in which State or local organizations may not have the desired expertise. Personnel serve as technical advisers to action agencies, such as APHIS, in times of disease outbreaks or vector-population explosions. Facilities are located at the Insects Affecting Man and Animals Research Laboratory, Gainesville, Fla.; Gulf Coast Mosquito Research Laboratory, Lake Charles, La., and Imported Fire Ant Research Laboratory, Gulfport, Miss.

Facilities for Research on Internal Parasites of Animals--The primary objective of the national parasite research program is to develop ways to prevent, control, or eradicate parasite infestations in livestock and poultry. The major unit in the program, the Animal Parasitology Institute, is the largest in the world devoted exclusively to research on parasites of food-producing animals. Parasitologists, veterinarians, chemists, entomologists, and immunologists cooperate in interdisciplinary approaches to achieve stated goals.

The ARS parasite research program provides for unbiased testing and evaluation of new antihelminthic drugs and proposed biological parasite control programs. The scientists also prepare and maintain two internationally known tools used by parasitologists worldwide: the Index Catalogue of Medical and Veterinary Zoology and the National Parasite Collection. Both are used nationally in studies of parasitism in livestock and poultry and are indispensable in efforts to develop parasite-control programs. Facilities are located at the Animal Parasitology Institute, Beltsville, Md., and the Regional Parasite Research Laboratory, Auburn, Ala.

Multidisciplinary Animal Production Research Centers--In addition to the major research effort at the Beltsville Agricultural

Research Center, ARS has several major research locations where large-scale research with dairy and meat-producing animals is conducted by multidisciplinary teams. Several of the research stations are the largest in the country, up to 56,000 acres in area, and their size enhances their ability to attract and retain high-quality scientists from many disciplines. The unique facilities and equipment range from sophisticated chambers for energy metabolism studies on individual animals to commercial-size production units for all classes of animals. The integrated programs conducted range from very basic research to studies in which large populations of animals are used in developing systems approaches to solve broad industry problems. Stations are strategically located to permit replicated studies in different physiographic situations to quantify interactions among genetic, nutritional, and management variables. Thus, programs of small stations become integrated parts of total programs and uniquely complement the programs of large stations.

Many of the large units are operated cooperatively with State agricultural experiment stations and serve as focal points for integrated research efforts, thereby enhancing the effectiveness of total research programs. In addition to the Beltsville Agricultural Research Center, Beltsville, Md., facilities are located at the U.S. Livestock Experiment Station, Miles City, Mont.; U.S. Sheep Experiment Station, Dubois, Idaho; Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, Nebr.; Southwestern Livestock and Forage Research Station, El Reno, Okla.; North Central Dairy-Forage Research Center, Madison, Wis.; and Brooksville Beef Cattle Research Station, Brooksville, Fla.

Poultry Production and Product Quality Laboratories--In addition to the poultry research programs at the Beltsville Agricultural Research Center, three major poultry-production and product-quality laboratories uniquely blend basic and applied studies using multidisciplinary team approaches. Interrelationships of the neuro-nutritional-endocrine systems are being investigated to improve turkey egg production. Unique cellular approaches are being used to study growth and the effect of stress on broilers. Agricultural engineers and poultry scientists are working on the effects of environment and management factors such as utilization of heat energy, limited area brooding, and control of environmental temperatures on the meat and egg production of chickens. Approaches being used to improve broiler product quality include investigating cage-rearing systems as a model for studying breast blisters and bone fragility; and studying ways to reduce the synergistic effects of several mycotoxins found in some feeds. Facilities are located at the Poultry Research Laboratory, Georgetown, Del.; Southeast Poultry Research Laboratory, Athens, Ga.; and South Central Poultry Research Laboratory, Mississippi State, Miss.

Postharvest Science and Technology Facilities

Animal Products Research Laboratories--Fundamental and applied research is conducted at nine laboratories across the Nation to evaluate and improve the quality and processing of animal products. Research conducted at one or more laboratories addresses processing, marketing, transportation, and distribution problems of meat, poultry, dairy products, freshwater fish, and eggs. Scientists study the biochemical, physiological, microbial, chemical, and physical changes in animals or their products during milking, egg collection, or transit, or after slaughter, and how these changes relate to genetic, production, or management practices or can be altered to protect or improve the quality and nutritional value of food produced from animals.

Techniques are developed for evaluating properties of tissues or products. Information is developed on biochemical/biophysical changes in animal tissues or products, and the mechanisms by which these are controlled or can be influenced become the basis for recommendations for maintaining and improving the quality of animal products. Knowledge of the effects of sodium on muscle protein solubility, meat emulsion stability, and the properties of muscle and milk protein could, for example, enable reduction in the amount of sodium added during processing. Research on animal products often requires an interdisciplinary approach to problems at a cellular and subcellular level. Such an approach involves food scientists, microbiologists, biochemists, physical chemists, and engineers. Often research supports Federal action agencies in their missions. Facilities are located at the Eastern Regional Research Center, Philadelphia, Pa.; Beltsville Agricultural Research Center, Beltsville, Md.; Richard B. Russell Agricultural Research Center, Athens, Ga.; Southern Regional Research Center, New Orleans, La.; ARS Bioengineering Research Laboratory, Columbia, Mo.; Northern Regional Research Center, Peoria, Ill.; ARS Transportation and Marketing Laboratory, College Station, Tex.; Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, Nebr.; and Western Regional Research Center, Albany, Calif.

Cotton Quality and Ginning Laboratories--These laboratories represent a research resource found nowhere else in the world. The specialized facilities and scientific staffs of the laboratories not only provide a valuable national resource for agriculture, but also support a major segment of the domestic textile industry and a sizable export market.

The Cotton Quality Research Station at Clemson evaluates the effects of proposed changes in the production/ginning sequence on the processing quality of cotton. The Southern Regional

Research Center is a central laboratory with instrumentation for evaluating small research samples of fiber and seed for cooperating ARS scientists at approximately 10 locations across the Cotton Belt. In addition, the laboratory provides analyses for the National Cotton Variety Testing Program conducted by ARS in cooperation with various State agricultural experiment stations. Together with the ginning laboratories, the two quality laboratories provide an essential research support service to the Cotton Division of USDA's Agricultural Marketing Service, which by law is responsible for grading and classifying the American cotton crop each year. The cotton quality facilities are located at the Cotton Quality Research Station, Clemson, S.C. and the Southern Regional Research Center, New Orleans, La.

Although all three ginning laboratories perform similar functions, each is essential to addressing the special genetic and harvesting problems pertaining to the three distinct cotton-growing regions of the United States: the humid, rainy areas of the Southeast and Mississippi Delta; the arid, High Plains of Texas; and the hot, dry, irrigated areas of the Southwest and West. Buildings and facilities are specially designed to handle, dry, and gin the seed cottons produced in these three separate regions of the Cotton Belt. The ginning facilities are located at the Southern Plains Cotton Research Laboratory, Lubbock, Tex.; Southwestern Cotton Ginning Research Laboratory, Mesilla Park, N. Mex.; and U.S. Cotton Ginning Laboratory, Stoneville, Miss.

European Marketing Research Center--The mission at this location is to conduct a research program that will contribute to increased efficiency in the marketing of U.S. agricultural products in Europe. Research is concerned with the identification and resolution of commodity quality problems, mainly in horticultural crops, that will reduce handling costs of and market losses in U.S. farm products. Facilities are located in Rotterdam, The Netherlands.

Family Resource Development Facilities--The Family Economics Research Group conducts research on the economic problems of families and the improved use of time, money, energy, and other resources by families. This group is located in Hyattsville, Md.

Scientists at the ARS Textiles and Clothing Laboratory conduct basic and applied research on the most effective use and care of textiles, clothing, and home furnishings available to consumers. The scientists disseminate research results in technical and popular publications. The laboratory shares a conditioning room with the Department of Textiles and Clothing at the University of Tennessee and, in addition to its own highly specialized textile-testing equipment, has access to

sophisticated equipment and instrumentation on the university campus. Facilities are located at the Textiles and Clothing Laboratory, Knoxville, Tenn.

Fruit and Vegetable Quality Research--Postharvest research is conducted at 12 locations throughout the United States where horticultural crops are produced, processed, and marketed. The laboratories conduct research on quality maintenance and loss reduction of horticultural crops and are located to provide direct access to growers, shippers, and receivers. To accomplish their mission, the laboratories study the effects of the preharvest environment unique to the growing area; effects of postharvest treatments for controlling pathological and physiological diseases; storage design, specifications, and environments; improved handling, packaging, and transporting methods; and chemistry and biochemistry of horticultural crops.

Research thrusts of some laboratories include energy conservation, waste reduction, and processing efficiency. Information is also developed for specifications and standards for raw and finished products. Facilities are located at the Agricultural Product Technology Research, Weslaco, Tex.; Fruit and Vegetable Chemistry Laboratory, Pasadena, Calif.; Citrus and Subtropical Products Laboratory, Winter Haven, Fla.; Food Sciences Laboratory, Raleigh, N.C.; Fruit and Vegetable Harvesting Research, East Lansing, Mich.; Red River Valley Potato Research Laboratory, East Grand Forks, Minn.; Market Quality and Handling Research Station, Miami, Fla.; Crop Protection and Production Research, Weslaco, Tex.; Market Quality and Transportation Research Laboratory, Fresno, Calif.; Production, Harvesting, and Handling of Tree Fruits Research, Wenatchee, Wash.; Commodity Treatment, Handling, and Distribution Research, Hilo, Hawaii; Horticultural Crops Quality Research, New Brunswick, N.J.; and Market Pathology Laboratory, Chicago, Ill.

Insect Control Laboratories--Ten insect control laboratories are distributed throughout the United States, so Federal scientists concerned with insect pests in stored commodities have access to the entire marketing system--from farm production to commercial storage, terminal export elevators, shipment and transportation, storage, milling, packaging, and overseas sales. These laboratories are equipped with chambers that can be used in commodity-treatment studies involving both vacuum and atmospheric test conditions. This equipment is generally not available anywhere else in the world.

Because of available laboratory facilities, investigations can proceed from studies at the basic level to studies on a scale large enough that practical problems can be identified and new

control techniques developed. Laboratory personnel include scientists, in various disciplines, in sufficient critical mass to facilitate interdisciplinary research. Facilities are located at the U.S. Grain Marketing Research Laboratory, Manhattan, Kans.; Stored Product Insects Research Laboratory, Fresno, Calif.; Hawaiian Agricultural Experiment Station, Hilo, Hawaii; ARS Fruit Fly Laboratory, Honolulu, Hawaii; Stored Product Insects Research and Development Laboratory, Savannah, Ga.; Tobacco Storage Insects Research Unit, Richmond, Va.; Insect Attractants, Behavior, and Basic Biology Research Laboratory, Gainesville, Fla.; Stored Product and Household Insects Laboratory, Madison, Wis.; Rice Experiment Station, Beaumont, Tex.; and Subtropical Horticulture Research Station, Miami, Fla.

Facilities for Research on Metabolic Safety of Agricultural Products--ARS programs constitute most of the Nation's research effort in the highly visible and increasingly important area of the metabolic safety of agricultural products. The required sophisticated equipment and facilities that could not be justified by smaller and less comprehensive units are concentrated in these facilities.

Specific objectives of the research are to (1) determine the metabolic fate of pesticides, agricultural chemicals, and drugs used to prevent and control diseases or to improve efficiency of animal production; (2) define chemical characteristics of and modes of action for and develop measures to prevent losses from poisonous plants and other naturally occurring toxicants; and (3) conduct toxicological and nutritional studies related to food and feed safety in production, processing, and distribution. Results are used by action agencies in programs to ensure the safety of animal products for consumers and to reduce the cost of production for producers. Facilities are located at the Beltsville Agricultural Research Center, Beltsville, Md.; Western Regional Research Center, Albany, Calif.; Richard B. Russell Agricultural Research Center, Athens, Ga.; Metabolism and Radiation Research Laboratory, Fargo, N. Dak.; Veterinary Toxicology and Entomology Laboratory, College Station, Tex.; and Poisonous Plant Research Laboratory, Logan, Utah.

National Peanut Research Laboratory--This laboratory, located in the heart of the Southeastern peanut production area, deals with problems associated with the quality and safety of peanuts. A multidisciplinary team, consisting of the essential scientific and engineering expertise needed to address problems in shelling, handling, grading, and storing of peanuts, provides a unique link among the farmer, small processor, and the food industry within the United States and abroad. The laboratory is located at Dawson, Ga.

U.S. Grain Marketing Research Laboratory--This laboratory provides the facilities, equipment, and critical mass of scientific and engineering expertise needed to address the full range of basic and applied research problems associated with maintenance of quality, reduction of losses, and safety in the handling and storage of grain. These capabilities are also used to resolve problems of the action agencies, particularly USDA's Federal Grain Inspection Service. This national facility complements the research capability of the milling school at Kansas State University and of the American Institute of Baking; together, they provide an unparalleled capability for resolving problems associated with our major agricultural commodities. The laboratory is located in Manhattan, Kans.

Soil, Water, and Air Sciences Facilities

Laboratories for Erosion and Sedimentation Studies--These laboratories have physical facilities--flumes, wind tunnels, raindrop towers, rain simulators, and field plots--that are unique for studying the physical processes involved in erosion, sediment transport, and sediment deposition. Multidisciplinary groups of scientists--engineers, soil scientists, chemists, agronomists, and biologists--work together to understand the processes involved in water and wind erosion, sediment transport, and sediment deposition and to develop methods for controlling erosion and sedimentation. Facilities are located at the National Erosion Research Laboratory, West Lafayette, Ind.; U.S. Big Spring Field Station, Big Spring, Tex.; and USDA Sedimentation Laboratory, Oxford, Miss.

National Tillage Machinery Laboratory--This laboratory is the only one in the United States in which soil bins and highly sophisticated instrumentation can be used to study the relationships among soil physical properties, tillage and traction devices, and machine performance. Studies are conducted on machine-mobility problems and on the effects of machine weights, traction, and flotation. The laboratory is located in Auburn, Ala.

Soil and Water Conservation Research Centers--These facilities are regional research centers that conduct soil and water conservation research applicable to the major land-use resource areas in which they are located. The facilities are federally owned and are located, in many instances, in areas where there are no universities. In some instances, cooperative efforts with State agricultural experiment stations are maintained. The centers are staffed with multidisciplinary teams, including soil scientists, agricultural engineers, plant physiologists, and agronomists, for research in broad problem areas. Some basic research is also conducted that has regional, national, and international significance. Facilities are located at the Appalachian Soil and Water Conservation Research Laboratory, Beckley, W. Va.; Plant, Soil, and Water Laboratory, Orono, Maine; North Central Soil Conservation Research Laboratory, Morris, Minn.; Northern Great Plains Research Laboratory, Mandan, N. Dak.; Central Great Plains Research Station, Akron, Colo.; Snake River Conservation Research Center, Kimberly, Idaho; Imperial Valley Conservation Research Center, Brawley, Calif.; Columbia Plateau Conservation Research Center, Pendleton, Oreg.; Soil and Water Conservation Research, Weslaco, Tex.; U.S. Southwestern Great Plains Research Center, Bushland, Tex.; Coastal Plains Soil and Water Conservation Research Center, Florence, S.C.; Southern Piedmont Conservation Research Center, Watkinsville, Ga.; Water Research Center, Sidney, Mont., and High Plains Grasslands Research Station, Cheyenne, Wyo.

U.S. Plant, Soil, and Nutrition Laboratory--This laboratory is one of the few in the world where scientists of different

disciplines are grouped together to conduct research on the geochemical and chemical processes involved in the cycling of nutritionally important substances in rocks, soils, plants, and animals. The research program includes factors controlling the distribution and availability of nutrients and the structure, synthesis, metabolism, and role of biologically important substances in the growth and development of plants, animals, and humans. The laboratory is located in Ithaca, N.Y.

Water Management Laboratories--These laboratories are located within the physiographic region where major problems of water management and associated soil problems exist. Each laboratory has a group of multidisciplinary scientists--soil scientists, plant physiologists, and engineers--who work together on basic relationships and conduct field experiments under regional climatic conditions.

Research with major crops grown in the area is conducted to develop improved water management technology for increasing water-use efficiency and minimizing soil and crop damage caused by salinity. Facilities are located at the Water Management Research Laboratory, Fresno, Calif.; U.S. Salinity Laboratory, Riverside, Calif.; U.S. Water Conservation Laboratory, Phoenix, Ariz.; Irrigation and Soil-Plant-Water Relations Unit, Fort Collins, Colo.; and Irrigation and Soil-Plant-Water Relations Unit, Grand Junction, Colo.

Watershed Research Centers--These centers, which are located in major climatological zones, consist of unique and intensively instrumented experimental facilities for evaluating the effects of crop and range activities on the environment and the effects of urbanization and mining on agriculture. Multidisciplinary teams of scientists and engineers use these research watersheds to assess the effects of land use and land treatment on water yield, flooding control, soil conservation, channel stabilization, and water quality for key physiographic regions. The research program includes fundamental studies on the movement of water, sediments, and agricultural chemicals. A major objective is the development and evaluation of improved land management and conservation technologies for use by action and regulatory agencies. Federal agencies benefiting directly from the research include the USDA Soil Conservation Service; U.S. Department of the Interior, Bureau of Mines and Bureau of Land Management; U.S. Army Corps of Engineers; and U.S. Environmental Protection Agency. Facilities are located at Southern Plains Watershed and Water Quality Laboratory, Durant, Okla.; North Appalachian Experimental Watershed, Coshocton, Ohio; USDA Sedimentation Laboratory, Oxford, Miss.; Grassland, Soil, and Water Research Laboratory, Temple, Tex.; Southwest Rangeland Watershed Research Center, Tucson, Ariz.; Northwest Watershed Research Center, Boise, Idaho; Southern Plains Watershed and Water Quality Laboratory, Chickasha, Okla.; Southeast Watershed Research Laboratory, Tifton, Ga.; Northeast Watershed Research Laboratory, University Park, Pa.; Watershed Research Unit, Columbia, Mo.; and Watershed Research Unit, Council Bluffs, Iowa.

APPENDIX A:
PRINCIPAL STATUTES

PRINCIPAL STATUTES RELATING TO AGRICULTURAL RESEARCH SERVICE ACTIVITIES

Subject or Popular Title	Public Law No.	Approval Date	Purpose
Organic Act of 1862	None	5/15/1862	In addition to establishing the Department of Agriculture, charges the Commissioner of Agriculture with the duty "...To acquire and preserve in his Department all information concerning agriculture which he can obtain by means of books and correspondence, and by practical and scientific experiments,..." This Act initially authorized the Department of Agriculture to perform a research function in relation to agricultural matters. (12 Stat. 387) (7 U.S.C. 2201, 2204)
Domestic Animals and Poultry	---	5/29/84	Establishes Bureau of Animal Industry to investigate and report on the condition of domestic animals and live poultry in the United States and on the causes and means of preventing diseases among them. (23 Stat. 31) (7 U.S.C. 391)
Dairy Industry	68-156	5/29/1924	Authorizes investigations of the dairy industry and dissemination of information for promotion of the dairy industry. (43 Stat. 243) (7 U.S.C. 402)
Dairy and Livestock Industry	69-490	7/3/26	Authorizes Secretary to establish a dairying and livestock experiment station at Mandan, North Dakota, for investigations and experiments in the dairy and livestock industries and for problems pertaining to establishment and development thereof. (44 Stat. 840) (7 U.S.C. 421)
Arboretum	69-799	5/4/27	Authorizes Secretary to establish a national arboretum for purposes of research and education concerning tree and plant life. (44 Stat. 1422) (20 U.S.C. 191-194)

Subject or Popular Title	Public Law No.	Approval Date	Purpose
Cotton	---	4/12/28	Authorizes Secretaries of Agriculture and Commerce to engage in technical and scientific research on American-grown cotton and its byproducts. (45 Stat. 426) (7 U.S.C. 423)
Dairy Industry	---	5/29/28	Authorizes Secretary to establish a dairy station at Lewisburg, Tennessee, for investigations, experiments, and demonstrations in the dairy industry and the problems pertaining to the dairy industry in the South. (45 Stat. 981) (7 U.S.C. 422)
Cotton Ginning	71-160	4/19/30	Authorizes Secretary to investigate ginning of cotton, to establish and maintain experimental ginning plants and laboratories, and to make tests and technical and scientific studies with respect thereto. (46 Stat. 24) (7 U.S.C. 424)
Soil Conservation Act	74-46	4/27/35	Authorizes Secretary to conduct surveys, investigations, and research relating to the character of soil erosion and the preventive measures needed and relating to economic use and conservation of land. (49 Stat. 163) (16 U.S.C. 590a)
Regional Research Laboratories	75-430	2/16/38	Authorizes Secretary to establish four laboratories, one in each major farm producing area, to conduct research into and to develop new scientific, chemical, and technical uses and new and extended markets for farm commodities and products and byproducts thereof. (52 Stat. 37) (7 U.S.C. 1292)
Poultry Improvement	78-425	9/21/44	Authorizes Secretary to cooperate with State authorities in the administration of regulations for the improvement of poultry, poultry products, and hatcheries. (58 Stat. 734) (7 U.S.C. 429)

Subject or Popular Title	Public Law No.	Approval Date	Purpose
Substitutes for Strategic Materials	79-520	7/23/46	Authorizes Secretary to make scientific, technologic, and economic investigations of the feasibility of developing domestic sources of supplies of any agricultural material or of using agricultural commodities for the manufacture of any material determined to be strategic and critical. (60 Stat. 599) (50 U.S.C. 98f)
Research and Marketing Act of 1946	79-733	8/14/46	Authorizes Secretary to conduct research into basic laws and principles relating to agriculture; to improve and facilitate the marketing and distribution of agricultural and the development of new and improved methods for the production, marketing, distribution, processing, and utilization of plant and animal commodities at all stages from the original producer to the ultimate consumer; to conduct research in the areas of human nutrition, development of new use and markets for agricultural commodities and agricultural resources (manpower, soil, plants, animals, and equipment); to conduct research relating to conservation, development, and the use of land, forest, and water resources; and authorizes the Secretary to enter into contracts with public or private organizations or individuals when in his judgment the research can be carried out more effectively, more rapidly, or at lower cost than if performed by Department personnel. (60 Stat. 1082) (7 U.S.C. 427, 1621)

Subject or Popular Title	Public Law No.	Approval Date	Purpose
Horse Breeding	80-494	4/21/48	Authorizes Secretary, in connection with transfer of any remount service to the Department, to improve breeding of horses suited to the United States. (62 Stat. 197) (7 U.S.C. 437)
Foot and Mouth Research	80-496	4/28/48	Authorizes Secretary to establish research laboratories and conduct and contract for research of foot-and-mouth and other animal diseases. (62 Stat. 198) (21 U.S.C. 113a)
Cattle Grubs	80-651	6/16/48	Authorizes Secretary to increase and intensify research and investigations into problems and methods relating to the eradication of cattle grubs. (62 Stat. 458) (21 U.S.C. 114c)
Commodity Credit Corporation Charter Act	80-806	6/29/48	Authorizes research relating to the conservation or disposal of commodities owned or controlled by the corporation in collaboration with research agencies of the Department. (62 Stat. 1070) (7 U.S.C. 612c)
Virgin Islands	82-228	10/29/51	Authorizes Secretary to establish, in the Virgin Islands of the United States, an agricultural research and extension service program. (65 Stat. 661) (48 U.S.C. 1409)
Agricultural Trade Development and Assistance Act	83-480	7/10/54	Authorizes the sale of agricultural commodities to friendly countries; authorizes the use of foreign currencies accruing from such sales for a variety of research activities. Sec. 104(b)(1) provides that foreign currency receipts may be used to develop new markets for U.S. agricultural commodities. Sec. 104 (b)(2) provides that foreign

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			currency receipts may be used to collect and disseminate scientific and technologic information, conduct research, and support scientific activities overseas. This Act includes programs of scientific cooperation between the United States and other countries, such as coordinated research against diseases common to all mankind or unique to individual regions. Sec. 104(b)(3) also authorizes support for programs of medical and scientific research, cultural and educational development, family planning, health, nutrition, and sanitation. (68 Stat. 454) (7 U.S.C. 1691)
Research Grants-Basic	85-934	9/6/58	Authorizes Federal agencies to make grants for basic scientific research at nonprofit institutions of higher education or at nonprofit organizations whose primary purpose is the conduct of scientific research. (72 Stat. 1793) (42 U.S.C. 1891)
Humane Slaughter Research	85-765	9/27/58	Authorizes Secretary to conduct, assist, and foster research, investigations, and experimentation to determine and to develop methods of slaughter, and methods for handling livestock in connection with slaughter, that will be humane. (72 Stat. 863) (7 U.S.C. 1904)
Housing Act of 1949	87-70	8/30/61	Authorizes Secretary to conduct research on the adequacy of existing farm housing and on current and prospective needs for farm housing, interrelation of farm housing problems with housing problems of urban and suburban areas, and other matters bearing on the provision of adequate farm housing. (75 Stat. 188) (42 U.S.C. 1476b)

Subject or Popular Title	Public Law No.	Approval Date	Purpose
Cooperative Research Projects	88-250	12/30/63	Authorizes ARS Administrator to enter into agreements and receive funds from State or other political subdivisions, organizations, or individuals. (77 Stat. 820) (7 U.S.C. 450a)
Agricultural Act of 1964	88-297	4/11/64	Authorizes Secretary to conduct a special cotton research program designed to reduce the cost of producing upland cotton in the United States (78 Stat. 174) (7 U.S.C. 14)
Research Grants-Special	89-106	8/4/65	Authorizes Secretary to make grants to State agricultural experiment stations, colleges, universities, and other research institutions and organizations and to Federal and private organizations and individuals for basic and applied research to further the programs of the Department. (79 Stat. 431) (7 U.S.C. 4501)
Tropical Research	89-808	11/11/66	Authorizes Secretary to conduct research in tropical and subtropical agriculture for the improvement and development of tropical and subtropical food products for dissemination and cultivation in friendly countries. (80 Stat. 1537) (7 U.S.C. 1736 (a)(4)
Federal Water Pollution Control Act	92-500	10/18/72	Authorizes Administrator of EPA, in cooperation with other Federal agencies, to develop comprehensive programs for water pollution control, and, in establishing National Programs therefor, to cooperate with other Federal agencies in conducting research, investigations, training, and information programs including, among other things, a comprehensive study and research program for preventing, reducing, and eliminating pollution from agriculture.

57-279 O - 87 - 34

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			Authorizes the Administrator of EPA, in consultation with the Secretary of Agriculture, to make grants for research and dissemination of information with respect to methods of preventing and of eliminating pollution from agriculture. (86 Stat. 816) (33 U.S.C. 1151)
Agriculture and Consumer Protection Act of 1973 (Farm Bill)	93-86 (Sec 809)	8/10/73	Authorizes and directs Secretary to carry out a comprehensive study and investigation to determine the reasons for the extensive loss of livestock sustained each year through their subjection to injury and disease during transport in interstate commerce for commercial purposes. Also authorizes and directs Secretary to conduct, in connection with such study and investigation, an intensive research program for the purpose of developing measures that can be taken to reduce materially the number of animals lost through injury and disease during their transport for commercial purposes. (This authority terminated after 4 years.) (87 Stat. 221) (7 U.S.C. 1305)
Agriculture and Consumer Protection Act of 1973 (Farm Bill)	93-86 (Sec 611)	8/10/73	Authorizes and directs Secretary to carry out programs to destroy and eliminate cotton boll weevils in infested areas of the United States and to carry out similar programs with respect to pink bollworms or any other major cotton insect if he determines that methods and systems have been developed to the point that success in eradication of such insects is assured. The Secretary shall carry out, through the Commodity Credit Corporation, the eradication programs authorized by this subsection. In carrying out insect eradication projects, he shall utilize the technical and related

Subject Popular Title	Public Law No.	Approval Date	Purpose
			services of appropriate Federal, State, and private agencies and cotton organizations. (87 Stat. 235) (7 U.S.C. 1305)
Agriculture and Consumer Protection Act of 1973 (Farm Bill)	93-86 (Sec 810)	8/10/73	Authorizes and directs Secretary to carry out regional and national research programs to reduce fertilizer and herbicide usage in excess of production needs, to develop wheat and feed grain varieties more susceptible to complete fertilizer utilization, to improve the resistance of wheat and feed grain plants to disease, and to enhance conservation and environmental qualities. (87 Stat. 238) (7 U.S.C. 1305)
National Arboretum	94-129	11/13/75	Authorizes Secretary to accept, receive, hold, utilize, and administer--on behalf of the United States--gift bequests or devises of real and personal property made for the benefit of the National Arboretum. (89 Stat. 683) (20 U.S.C. 195)
International Development and Food Assistance	94-161 Title II Sec 214	12/20/75	Transfers Farmer-to-Farmer Program from the Secretary of Agriculture to the President. (89 Stat. 849) (22 U.S.C. 2151)
Surface Mining Control and Reclamation Act of 1977	95-87	8/3/77	Sets environmental-protection performance standards to be met at all major surface mining operations for coal; provides for joint responsibility and enforcement by the States and the Federal Government; establishes a self-supporting Abandoned Mine Reclamation Fund to restore land ravaged by uncontrolled mining operations in the past; protects certain land regarded as unsuitable for surface mining; establishes mining and mineral resource institutes and provides

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			funds for coal research laboratories and graduate fellowships; and provides for a transfer of funds to USDA for technical and financial assistance to landowners entering into long-term agreements for reclamation purposes. (91 Stat. 445) (30 U.S.C. 120)
Food and Agriculture Act of 1977 (Farm Bill)	95-113 (Title 14)	9/29/77	Assigns USDA the lead agency role with respect to national food and agricultural science. It also provides for coordination, expanded efforts in priority areas, and widening participation in research and education beyond the USDA and Land Grant University system. The law provides for expansion of USDA involvement in agricultural solar energy research, development, and demonstration, and grants USDA authority to be a full participant in nutrition research and education and in internationally related food and agricultural research and education. Establishes several coordinating and policy committees within USDA (91 Stat. 981) (7 U.S.C. 3101)
Soil and Water Resources Conservation Act of 1977	95-192	11/18/77	Provides that the Secretary shall appraise, on a continuing basis, the soil, water, and related resources of the Nation; develop and periodically update a program for furthering the conservation, protection, and enhancement of the soil, water, and related resources of the Nation; and provides that the President shall transmit periodically, to the Congress, the appraisal of the program as required by this Act. (91 Stat. 1407) (16 U.S.C. 2001)
Clean Water Act of 1977	95-217	12/27/77	Exempts irrigation return flows from the permit system requirements of section 402 of the Federal Water Pollution Control Act of 1972 and

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			defines them as nonpoint sources to be considered in areawide waste treatment management plans. (91 Stat. 1566) (33 U.S.C. 1251)
Surface Mining Control and Reclamation Act of 1977, Amendments	95-343	8/11/78	Authorizes funds for FY 1979 and 1980 for surface mining control and reclamation. (92 Stat. 473) (30 U.S.C. 1302)
Roman L. Hruska Meat Animal Research Center, Nebraska Designation	95-436	10/10/78	Designates the Meat Animal Research Center, located near Clay Center, Nebraska, as the "Roman L. Hruska Meat Animal Research Center." (92 Stat. 1054)
Public Lands Relinquishment of Jurisdiction	95-441	10/10/78	Authorizes Secretary to relinquish exclusive legislative jurisdiction over lands or interests under his control. (92 Stat. 1064) (7 U.S.C. 2268)
Gifts and Property Acceptance and Administration by Secretary of Agriculture	95-442	10/10/78	Authorizes the Secretary to accept and administer, on behalf of the United States, gifts or devises of real and personal property for the benefit of the Department of Agriculture or of any of its programs. (92 Stat. 1065) (7 U.S.C. 2269)
Humane Methods of Slaughter Act of 1978	95-445	10/10/78	Prohibits inhumane slaughtering of livestock within the United States and the importation of any meat or meat products unless such livestock are slaughtered in a humane manner. (92 Stat. 1069) (21 U.S.C. 601)
Carl Hayden Bee Research Center Designation	95-446	10/10/78	Designates the United States Department of Agriculture's Bee Research Laboratory in Tucson, Arizona, as the "Carl Hayden Bee Research Center." (92 Stat. 1071)

Subject or Popular Title	Public Law No.	Approval Date	Purpose
W. R. "Bob" Poage Pecan Field Station, Texas Designation	95-451	10/11/78	Designates the U.S. Department of Agriculture's Pecan Field Station in Brownwood, Texas, as the "W. R. 'Bob' Poage Pecan Field Station." (92 Stat. 1100)
Water Research and Development Act of 1978	95-467	10/17/78	Promotes a more adequate and responsive national program of water research and development. (92 Stat. 1305) (42 U.S.C. 7801)
Food and Agriculture Act of 1977, Amendment (Farm Bill)	95-547	10/28/78	Amends section 1445(b) of the Food and Agriculture Act of 1977 to modify the formula for distribution of funds authorized thereunder for agricultural research. (92 Stat. 2063) (7 U.S.C. 3222)
Native Latex Commercialization and Economic Development Act 1978	95-592	11/4/78	Authorizes the Secretaries of Agriculture and Commerce to coordinate basic and applied research, technology development, and technology transfer leading to effective and economical methods for large-scale culturing of plantations and to the extraction of latex. (92 Stat. 2529) (7 U.S.C. 178)
Energy Security Act	96-294	6/30/80	Authorizes funds to establish the production of synthetic fuels, gasohol, solar energy, renewable resources, and geothermal energy; to establish an energy conservation program and energy supply targets; and to extend the Defense Production Act until September 30, 1986. Title II establishes a comprehensive biomass and alcohol fuels program and urban waste program. Part A of this title contains new programs for USDA, including forestry. Title VII calls for two research programs: (1) Acid Precipitation and (2) Carbon Dioxide. The acid precipitation study sets up an

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			interagency task force jointly chaired by National Oceanic and Atmospheric Administration, EPA, and USDA. The 10-year study includes identifying sources contributing to, monitoring levels of, and formulating recommendations to alleviate acid precipitation. (94 Stat. 611) (42 U.S.C. 8701)
Rural Development Policy Act of 1980 Amendment	96-355	9/24/80	Amends Sec. 2 of the Rural Development Act of 1972 (Public Law 92-419; 86 Stat. 657) by adding a new section, Section 607, which directs the Secretary to assume a leadership role in coordinating a nationwide rural development program by developing a rural development policy, preparing and implementing a rural development program policy, preparing and implementing a rural development strategy and updating it annually, and maximizing coordination of Federal programs affecting rural areas. Reauthorized Title V until 1981. (94 Stat. 1171) (7 U.S.C. 2201)
National Aquaculture Act of 1980	96-362	9/26/80	Provides for a strong national policy statement promoting aquaculture in the United States and calls for the development of a National Plan for Aquaculture, thus encouraging activities and programs in both the public and private sectors of the economy. The bill further provides for studies to investigate the need for financial programs and to examine how we reduce undue regulatory constraints that may face the aquaculture industry. (94 Stat. 1198) (16 U.S.C. 2801)
Animal Cancer Research Act	96-469	10/17/80	Authorizes the Secretary to conduct a program of basic research on cancer in animals and birds at appropriate

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			facilities within USDA, or by grants to other qualified research facilities, and requires consultation and coordination of animal cancer research between the Department of Agriculture and the National Institutes of Health until the end of Fiscal Year 1986. (94 Stat. 2235) (7 U.S.C. 3901)
Stevenson-Wydler Technology Innovation Act of 1980	96-480	10/21/80	Establishes a national policy on the transfer, to local and State governments and to the private sector, of federally funded technology emanating from agencies and laboratories. The law requires each Department to establish, in selected Federal laboratories, an Office of Research and Technology Applications and to mobilize all Federal laboratories in support of technology transfer. (94 Stat. 2311) (15 U.S.C. 3701)
Robert Wentworth Harned Laboratory Designation	97-77	11/13/81	Redesignates the U.S. Department of Agriculture Boll Weevil Research Laboratory, located at Starkville, Mississippi, as the "Robert Wentworth Harned Laboratory." (95 Stat. 1069) (7 U.S.C. 1446)
Agriculture and Food Act of 1981 (Farm Bill)	97-98 (Title XIV)	12/22/81	Extends by four years the Congressional authorization to provide adequate support to funding for research, extension, and teaching aimed at continued gains in the productivity of the agricultural sector. The legislation also provides for strengthening the research and extension partnership between the U.S. Department of Agriculture and the Nation's land-grant colleges and universities. It also expands the scope of activities to include aquaculture, rangeland management, and a Dairy Goat Research Center. Other provisions include authorization for a research extension program

Subject or Popular Title	Public Law No.	Approval Date	Purpose
			concentrating on rural development and small farm problems; establishment of a Soybean Research Advisory Institute within USDA; a requirement that the Secretary of Agriculture include, in a regular annual report due January 1, 1984, a long-term needs assessment for food, fiber, and forest products; a directive to the Secretaries of Agriculture and Health and Human Services to report within 180 days on plans for a human nutrition research and information management system; an authorization for a building fund of $10 million per year for the next five years for the 1890 institutions; a requirement that the Hatch Act be funded at a level at least equal to 25 percent of the funding level for all agricultural research; and a requirement that an Assistant Secretary of Agriculture be appointed to administer the provisions relating to the research, extension, and teaching activities of the Department. (95 Stat. 1213) (7 U.S.C. 1281)

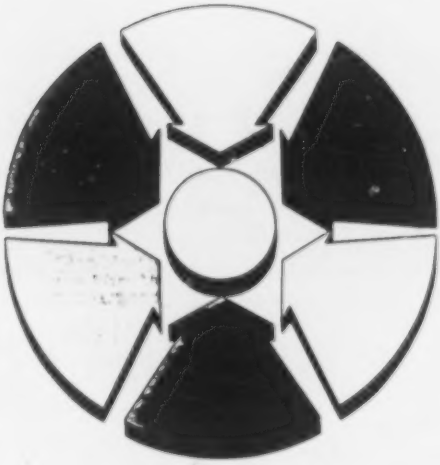
Agricultural Research Service Program Plan



Goal:
Through fundamental and applied research, ARS seeks to provide the means for solving the technical food and agricultural problems of broad scope and high national priority as required to ensure, perpetually, an adequate supply of high-quality food and fiber for the American people and for export.

Objectives:
Develop the means for—

1. Managing and conserving the Nation's soil and water resources for a stable and productive agriculture;
2. Maintaining and increasing the productivity and quality of crop plants;
3. Increasing the productivity of animals and the quality of animal products;
4. Achieving maximum use of agricultural products for domestic markets and export;
5. Promoting optimum human health and well-being through improved nutrition and family resource management; and
6. Integrating scientific knowledge of agricultural production, processing, and marketing into systems that optimize resource management and facilitate transfer of technology to users.

Foreword

The Agricultural Research Service (ARS) of the U.S. Department of Agriculture (USDA) must respond to the needs of our complex agricultural enterprise. Agriculture accounts for about 20 percent of the Nation's business volume and employment and, in 1981, accounted for about 19 percent of its exports, but it does not always provide farmers with a reasonable return from their investments of land, labor, and capital. Our agricultural enterprise is committed to supplying the needs of consumers, at home and abroad, with wholesome, nutritious food and other farm products at affordable prices. In continuing to meet that commitment, U.S. agriculture faces an array of major challenges, which include conserving our natural resources, improving the efficiency of production, and increasing the use of farm products.

I asked ARS scientists and the National Program Staff (NPS) to devise a strategy that would provide, through research, the means by which U.S. agriculture could meet those challenges. In response, they developed this document, the ARS Program Plan. The Plan records the best thinking, of approximately 500 ARS scientists and the members of the NPS, on how ARS can meet agriculture's short- and long-term needs most effectively and efficiently. As my part in strategic planning, I revised the management philosophy of ARS and formulated the policies for the Implementation Strategy. The policies establish the principles and standards that will guide the Agency in following the Program Plan. They also provide guidelines for collaboration and teamwork among ARS employees in line and staff positions. In accordance with those policies, I will operate the ARS as a managed activity, coordinated by plan.

The Program Plan provides for close coordination with other research organizations in and out of USDA, the action agencies in USDA, and other organizations that use our research findings. I want to emphasize the special working relationships between ARS and the State Agricultural Experiment Stations. Cooperative research programs must continue their valuable contributions to the development of science for agriculture.

The Program Plan includes programs for meeting future, as well as present, needs of U.S. agriculture. On the basis of recommendations by the scientists and the NPS, and guided by the policies, a Six-Year Implementation Plan is being prepared. In it we identify the programs of highest priority that ARS will support first. We are developing the projected resource allocations for those high-priority research programs. That information will guide decisionmaking by management at all levels in ARS. Programs will be evaluated systematically to identify areas of significant progress, major constraints to further progress, emerging research problems and opportunities, and research that can be discontinued. Such evaluations will guide me in managing the physical, financial, and human resources of ARS.

We will measure the success of our strategic planning by our progress in the ARS mission of producing new knowledge and technologies for the Nation's food and agricultural enterprise. Evidence of our progress will be outstanding, innovative research that meets the needs of U.S. agriculture and that, in turn, will help sustain and improve the well-being of our people for generations to come.

The Agricultural Research Service Program Plan

Summary

The Agricultural Research Service Program Plan represents the best thinking of about 500 scientists and members of the National Program Staff (NPS), Agricultural Research Service (ARS), U.S. Department of Agriculture (USDA), who participated in the strategic planning process. The Plan reflects the concern of the scientists about supplies of high-quality food and other farm products at affordable prices for U.S. citizens and for export, about the economic welfare of the U.S. agricultural enterprise, and about conserving the Nation's natural resources. Members of the NPS organized the ideas and recommendations of scientists into this Program Plan.

The goal of the Plan is to ensure, perpetually, an adequate supply of high-quality food and fiber for the American people and for export. The six objectives that will lead to the ARS goal deal with conserving and managing natural resources, increasing the productivity of plant crops and of livestock, marketing farm products efficiently, improving the nutrition of people, and developing agricultural systems. Each objective is presented in one of the six main sections of the Program Strategy. In each section, background information, needs that justify the research proposed, and the potential benefits of the research are reported. Research approaches and specific elements for each approach are listed and discussed. In the sections for the objectives, ARS scientists propose using the most advanced physical, chemical, and biological technologies to meet the short- and long-term needs of U.S. agriculture and, ultimately, to meet the needs of people worldwide. Those proposals provide a wealth of ideas for sparking new ARS programs well into the next century.

For the ARS Implementation Strategy of strategic planning, the Administrator established the six major policies that define his courses of action for operating ARS as a federally funded and managed agency. He will operate ARS as a managed activity coordinated by plan. The Deputy Administrator and the NPS are responsible for and are now developing the Six-Year Implementation Plan. The policies provide for the major functions needed for achieving the six objectives of the Program Strategy, and they assign the responsibility for establishing priorities in the Six-Year Implementation Plan. Regional administrators are responsible for operational plans, and the Administrator has overall responsibility for coordination and execution of the programs. The Deputy Administrator is responsible for systematic evaluation of programs. The ARS is continuing its research in, and its exchange of technology with, foreign countries. The policies were designed to ensure that ARS, the primary research agency of USDA, functions effectively and efficiently.

By policy, the ARS Program Plan provides an optimum balance between the fundamental research needed for long-term solutions to agricultural problems and the applied research needed by action agencies in the Department and by other users of research to carry out their responsibilities. The Plan stresses the innovation and creativity that characterize the ARS research program. By their strategic planning, ARS scientists ensure that their Agency can mobilize its talent and facilities to develop the science needed to meet present and future challenges to U.S. agriculture.

Research has revolutionized American agriculture. No aspect has gone untouched, from the planting of superior seeds to the ultimate consumption of wholesome and nutritious food. Farmers and agribusinesses apply research findings in the use of natural resources and produce an abundance of food and fiber unmatched in the history of mankind. Agricultural productivity, which has increased a phenomenal 240 percent in the past 50 years, has freed millions of people for other kinds of work and accounted for much of the industrial growth in the United States. Today, about 22 million people work in some phase of agricultural production, processing, and distribution and make agriculture and its related industries our largest business. Americans spend a smaller proportion of their income on food—about 16 percent—than do people in any other country.

Challenges to Agriculture

Despite the past performance record of American agriculture and the current surpluses of some crops, many studies and assessments question its ability to meet future demands for food and other agricultural products. The main challenges are as follows:

- The United States has become the residual supplier of agricultural commodities for a growing world population. In 1981, crops harvested from nearly 40 percent of all U.S. acreage and valued at about $44 billion were destined for foreign markets. World food production must double in the next 40 years to meet projected demands.

- Our base of natural resources has declined in quantity and quality because groundwater supplies have diminished, farmlands and irrigation water have been lost to other uses, and excessive erosion of top soil continues from about a third of our farmlands. Additional land and water supplies can be developed, but their costs will be higher and their productivity lower than for those now in use.

• The productivity of key components of agriculture is beginning to peak or flatten out. Average farm yields of crops such as cotton, rice, sugarcane, and dry edible beans have not increased in many years, and yields of other crops may also be peaking. The productivity of farmers' inputs actually declined 7 percent during the 1970's. That trend is continuing into the 1980's; farmers' costs for inputs are increasing and the productivity of the inputs is generally decreasing.

• We face an increasing number of new constraints that include high costs of petroleum and natural gas and of products, such as fertilizer, that are derived from them; increasingly erratic weather patterns in the past decade; only fair to poor condition of about 60 percent of our rangelands; increasing regulation of agricultural chemicals and processes; and many actual or potential environmental constraints, such as air pollution and declining water quality.

• Improving the economic health of agriculture and of its independent entrepreneurs is a major challenge. To adopt new technologies and to meet the anticipated needs of future generations, agricultural business must be economically strong.

All the energy that is essential for the growth of plants—and, therefore, for the production of food and fiber—comes from the sun. Green plant tissues capture the sun's energy in chlorophyll and, by photosynthesis, make the chemical compounds that we eventually use for food, clothing, shelter, and other purposes. However, plants capture only a small fraction of the sunlight available on earth. Animals convert plant materials into meat, milk, and other foods. However, humans eat, as primary foods, only a small fraction of the plant materials produced; most plants are grown as food for animals. To meet projected needs of the world's growing population and to enhance its standard of living, scientists must optimize photosynthesis by plants and the conversion of plants to animal products.

Because the land area suitable for growing crops is limited, food and fiber production with existing technologies and management practices will also be limited. Are we approaching that limit? Some experts argue that we may already have exceeded the long-term, sustainable productive capacity of the earth. Others argue that we have barely scratched the surface of productive capacity.

Scientists who question the sustainability of current agricultural capacity point out its heavy dependence on energy from fossil fuels that store the energy captured through photosynthesis by green plants that lived millions of years ago. Our food production, therefore, depends not only upon the energy available from the sun daily, but also upon prehistoric sunlight stored in fossil fuels. As we deplete those nonrenewable energy reserves, the potential for agricultural production from them will be lost or become increasingly more expensive.

About half the original topsoil has been removed from U.S. farmlands by erosion. About one-third of the ground water used for irrigation in the 17 Western States is being pumped from aquifers faster than they can be recharged. Other causes for concern include loss of farmlands and irrigation water to other uses, depletion of phosphate

reserves, salinization of land and water, loss of potentially valuable germplasm, and adverse effects of pollutants such as acid rain.

The yields of some crops are not increasing. Most of the people in the world eat rice and wear cotton clothes. Despite high inputs of fossil fuels and technology, neither rice nor cotton yields have increased appreciably in the United States since 1965. Their rates of yield increase are stalled (fig. 1). Although future demands for cotton products and rice are not clear, most estimates indicate that demands will increase. How then will the yields and production efficiency of cotton and rice be increased?

Scientists and others who argue that we have much unused productive capacity make several claims. They point out that the primary goal of past research was to increase production per unit of land and of labor, the two most costly production factors. Thus, they argue, the past record may not be a valid basis for accurately predicting the ability of scientists to improve the yields of crops and the efficiency of resource use in the future. Those people claim that because farmers' average crop yields are only a third or less of maximum experimental crop yields, considerable biological potential remains to be exploited. They also claim that, so far, we have always found ways to increase productivity. A novel claim is that the complex of modern technologies provides a new resource—technology itself—that generates "science power." Unlike natural resources, technology is manmade and its proponents think that science power could increase agricultural productivity indefinitely, as depicted for the last 50 years in figure 2.

The concept of science power piques our imaginations and heightens our expectations. For example, dare we expect that, when conventional techniques have failed, scientists could use science power to produce plants that capture extra sunlight or to produce cereal crops that fix nitrogen directly from the air? Dare we expect that they will use science power to slow the drain on our natural resources or to harness new sources of energy as substitutes for fossil fuels? We can imagine that those feats—and others—are possible. If we expect to realize such feats, however, we must gain the fundamental knowledge and experience necessary to address the constraints that limit agricultural productivity today. We cannot predict accurately the shape that the productivity growth curve will assume by the year 2000. Nor can we predict that science power will continue indefinitely to support growth at the rate indicated by extrapolation of figure 2.

Of the growth in overall productivity attributed to science power, how much accrued from innovation, without extra drain on our natural resources? The use of improved crop varieties does increase yield, but often the increase is at least partially due to their use of extra nitrogen fertilizer. Examples are the short, stiff-straw rice and wheat cultivars that resist lodging even when highly fertilized. The data indicate that those and other high-yielding crops do not use fertilizer more efficiently than do other crops, they just use more of it. Some crop breeders think that we have largely exploited the advantages of the short, stiff-straw characteristic in those crops. Many authors report that past increases in production depend, in fact, upon increased use of fossil fuels, water, chemicals of many kinds, and other resources.

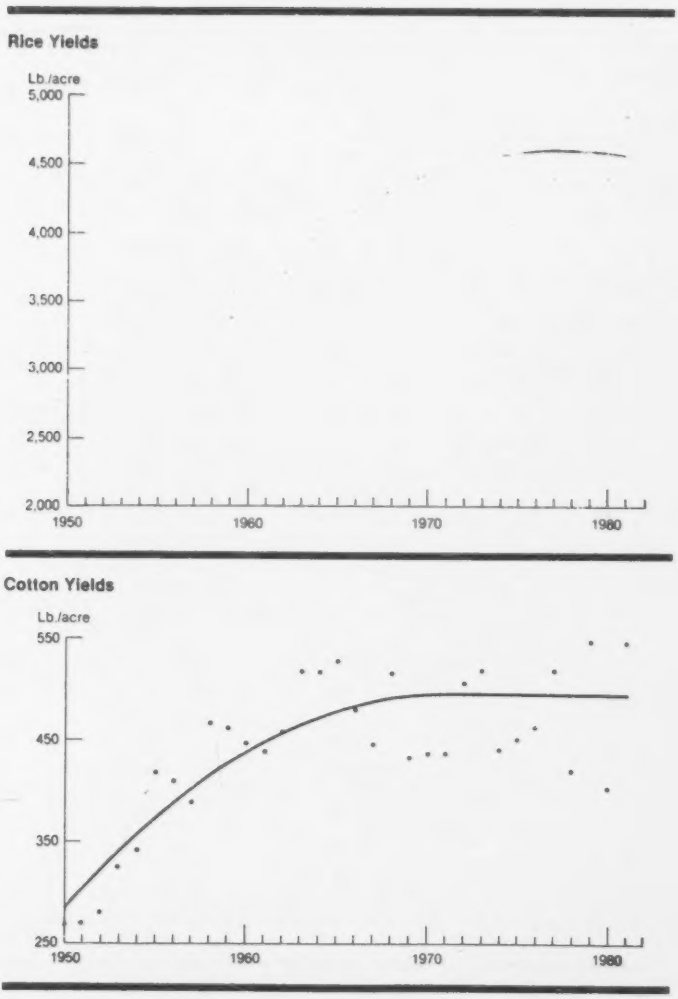

FIGURE 1.—Yield trends for rice and cotton (from Needs Assessment Committee Report, "Future Needs for Agricultural Products and Resources," 1981).

Related to the question of sustaining long-term growth in productivity is the need for year-to-year stability. Because so little food is stored worldwide each year, and because the differences between shortages and surpluses often are less than 10 percent of average production, our ability to feed ourselves and to export food and feed crops is determined to a considerable extent by production in the worst years, rather than by that in average years. Production stability is related more closely to weather than to any other factor, and the erratic weather patterns of the past decade probably are more typical of the norm than are the stable patterns of the 1950's and 1960's. As the world population grows and production potentials are reached, we may not have the crop surpluses of the past to tide us over severe droughts like the one in 1980.

Prediction of the effects of the main challenges to agriculture on supplies and costs of food and feed would be speculative. Most experts seem to agree that the demand for export of large quantities of grains and other farm products will continue. However, our land reserves will be used fully in the next 20 to 30 years, and any further increases in supplies of food, feed, and fiber must come from increased productivity of our natural resources, our crops and livestock, and our marketing systems. Even with low-demand projections, the required rates of productivity translate into dramatic numbers—275 bushels per acre of corn by the year 2000 and 385 bushels per acre by the year 2050. Such yields equal or exceed the highest experimental yields ever produced and are about three times as high as average farm yields (110 bushels of corn per acre in 1981). With

U.S. Agricultural Productivity Growth During the Past 200 Years

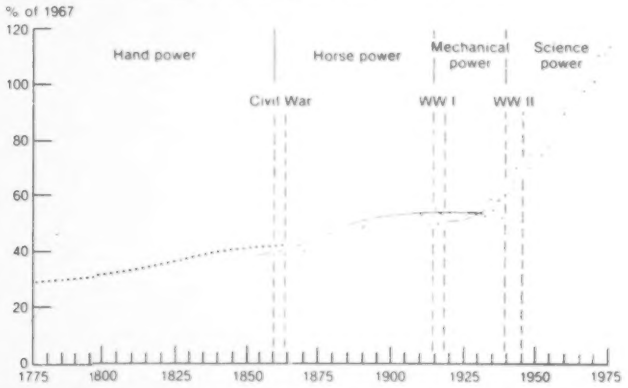

FIGURE 2.—Growth of U.S. agricultural productivity during the past 200 years. (Lu, Yau-Chi, Philip Cline, and Leroy Quance. Prospects for Productivity Growth in U.S. Agriculture. USDA Agricultural Economic Report No. 435, Sept. 1979.)

high-demand projections, the yields required would be higher than the limits imposed by the photosynthetic capacity of today's crops. Production of crops and livestock is only part of the story. Raw agricultural products must be marketed and processed into useful forms. Only through radically improved technology can we develop the marketing systems needed for efficiently handling, storing, and processing such huge quantities of food and fiber.

The success or failure of science as a whole might well be judged by the success or failure of the agricultural sciences during the next few decades. Without adequate scientific knowledge, we have little hope of responding rationally to the risks and uncertainties of an unpredictable future.

The Challenge to Agricultural Research

Many groups fund and perform research and development for agriculture. The major contributors and the percentage of funds from each are shown in figure 3. The private sector provides the major share of the funding, predominantly in the physical sciences and engineering, for developing processes and products that yield a profit in the marketplace. In contrast, public research funds are concentrated in biological sciences and technology, where profits are not so easily captured. Public funds also support a larger proportion of long-term and basic research than do funds provided by industry. Public funds, both State and Federal, are crucial for continued support of higher education in all phases of agriculture where research is an integral and essential part of advanced training in the biological, social, and physical sciences and in engineering. The "other Federal" category includes funds for agencies such as the Forest Service, Economic Research Service, and Cooperative State Research Service in the U.S. Department of Agriculture (USDA), as well as for many agencies outside the Department.

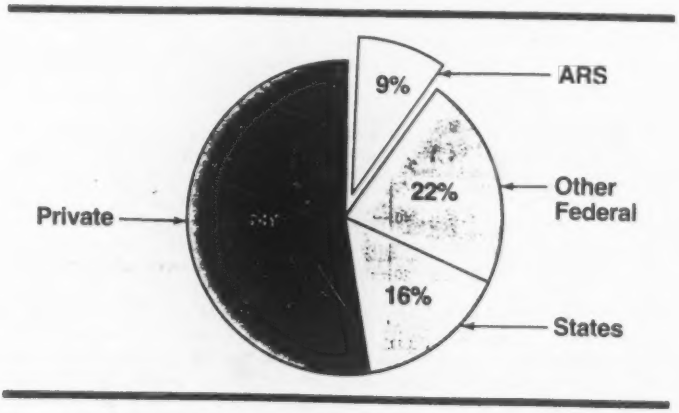

FIGURE 3.—Public and private funds for U.S. food and agricultural research.

The Agricultural Research Service (ARS) is the Department's principal intramural research agency. It has long-standing working relationships with the other research agencies in the Department, the State Agricultural Experiment Stations, and the private research sector. The ARS also works closely with the action agencies in the Department and serves as the research arm for many of them. Interagency programs within the Department are critical in such areas as soil and water conservation, range improvement, control of plant and animal diseases, and food safety.

The mission of the ARS is—

> To plan, develop, and implement research that is designed to produce the new knowledge and technologies required to assure the continuing vitality of the Nation's food and agricultural enterprise. As a Federal research agency, ARS (1) addresses problems that are of legitimate national concern, (2) conducts research that is appropriate for the Federal Government, and (3) exploits the unique capabilities of ARS scientists and the facilities they operate—a combination that forms an integrated and coordinated national resource that is not duplicated by others in the full U.S. agricultural research and development system.

In fulfilling its responsibility for assuring that the Nation has adequate supplies of high-quality food and fiber, the Department supports a wide range of research and educational activities, but it is primarily the ARS that must address the long-range, high-risk problems of national and international concern. The two overriding objectives of the Administration are bolstering national security and strengthening the national economy. No scientific effort is more critical to serving both objectives than is the mission-oriented research of ARS. A flagging agricultural technology—costly and erratic food supplies and depleted natural resources—is not in the national interest. Food is as critical to national security as are armaments. Agriculture, the Nation's largest industry, is in serious economic difficulty, and ways must be sought to restore its prosperity and to ensure its long-term stability.

The resources of ARS provide a sound foundation for developing the means by which agricultural technology may meet the enormous demands of future years. Those resources are as follows:

- *Critical mass of scientific capabilities,* comprised of more than 2,700 scientists and engineers, plus technical support staff, with the knowledge, technical expertise, and specialized scientific equipment to respond to broad regional and national problems.

- *Unique facilities and laboratories,* developed for all the disciplines demanded by agricultural research. Many are highly specialized laboratories; for example, those for the study of exotic diseases of plants and animals. Facilities are located strategically across the major farm and rangeland ecosystems and climatic zones of the United States. The world's largest multidisciplinary agricultural research center is at Beltsville, Md.

- *Organizational capability and central management to assemble resources,* including interdisciplinary teams to address broad geographic problems, the research needs of action agencies and other Federal organizations, and other high-priority needs for knowledge and technology. ARS has institutional arrangements for working with State Agricultural Experiment Stations, industrial research institutions, and others to bring outside talents and resources to bear on problem solving. The ARS also maintains international activities to mobilize the talents of foreign scientists and laboratories.

- *Unique germplasm collections and repositories of species of agricultural importance,* including world collections of most of the major crop plants and many potential new crops, clonal repositories, disease-free seed stocks, collections of microbes and insects, and unique herds and flocks of animals.

The ARS is challenged to manage its resources efficiently and effectively. In response to that challenge, it must assure the Nation that the Federal commitment to agricultural research is sufficient to deliver the science and technology that are essential to meet the continuing, long-term needs of national and world agriculture.

e ARS Program Plan

As illustrated in figure 4, the ARS Program Plan is the result of strategic and operational planning. This document describes the Program Strategy of strategic planning. It also introduces the Implementation Strategy by presenting the six major policies of the Agency. Based on the Program Strategy and those policies, a Six-Year Implementation Plan and resource projections are being prepared. They, in turn, will guide operational planning, resource allocation, and program execution for achieving the six objectives. Thus, this Program Plan will enable the ARS to mobilize its resources—talent and facilities—in a united effort to achieve its goal and to serve the U.S. agricultural enterprise.

As a Federal agency, ARS concentrates on research problems that are high-risk, long-range, and of national or regional scope. Such research requires unified planning, continuity of effort, a stable scientific environment, and the ability and flexibility to commit the necessary resources to high-priority needs that only a centrally funded, national organization can address. In accordance with its mission, the ARS also must continue to meet its responsibilities to support quarantine and other action programs, foreign policy initiatives, important national and international germplasm collections, and special emergency programs of regional or national significance. The need to integrate those responsibilities into the ARS program, with its disciplinary research in support of the six objectives, emphasizes the requirement for a planned and centrally managed operation.

Few people realize the technical and scientific complexity of the business of food and agriculture. The research programs of ARS must address that complexity in a logical and consistent manner. The success of the Nation's agriculture is influenced by an array of complex problems that can be physical or biological, and the scientific responsibilities of ARS must span the whole array for effective discharge of its assigned responsibilities.

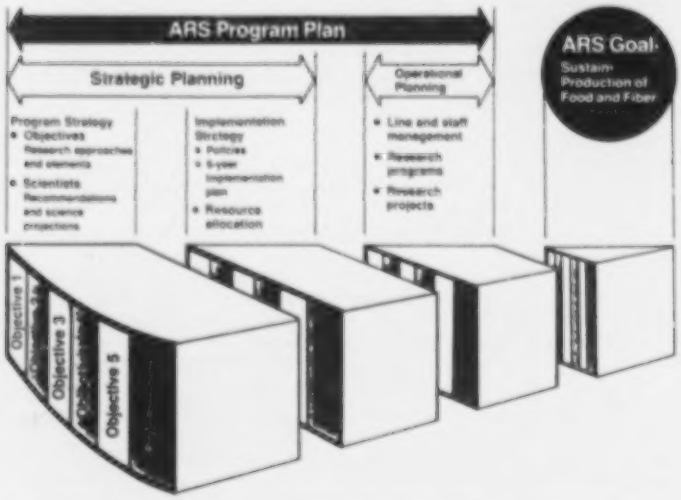

FIGURE 4.—The relationship of strategic and operational planning to the ARS goal and objectives.

As illustrated in figure 5, the Program Strategy of the ARS Program Plan was designed around a goal that is addressed by six objectives; progress on the objectives will result in progress toward the goal. With that design, all levels of organization, from individual laboratories to headquarters staffs and administrators, can use the Plan; all phases of research—ranging from studies of plant and animal genes to studies of bread and meat—can contribute to the goal.

Planning by ARS is an ongoing process, and through annual updating to reflect changes in priorities, appropriations, personnel shifts, and new research findings, the Plan will remain a dynamic document. The Six-Year Implementation Plan will be used by management as a baseline for evaluating progress and reallocating resources.

Line managers and members of the National Program Staff (NPS) developed the following goal and objectives for the Agency. They considered authorizing legislation, policy statements from the Secretary and the Assistant Secretary for Science and Education of the Department, and the common program structure developed by the Joint Council on Food and Agricultural Sciences.

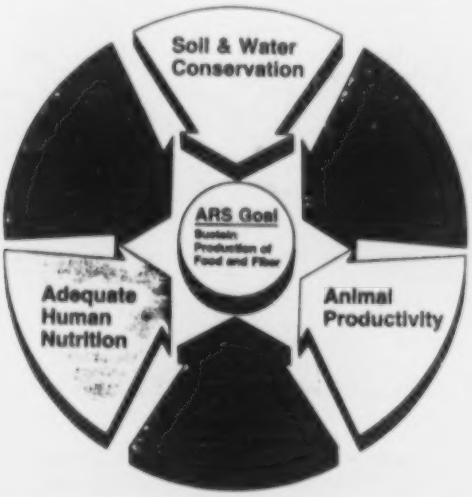

FIGURE 5.—The ARS Program Strategy—goal and objectives.

Goal:
Through fundamental and applied research, ARS seeks to provide the means for solving the technical food and agricultural problems of broad scope and high national priority as required to ensure, perpetually, an adequate supply of high-quality food and fiber for the American people and for export.

Objectives:
Develop the means for—

1. Managing and conserving the Nation's soil and water resources for a stable and productive agriculture;

2. Maintaining and increasing the productivity and quality of crop plants;

3. Increasing the productivity of animals and the quality of animal products;

4. Achieving maximum use of agricultural products for domestic markets and export;

5. Promoting optimum human health and well-being through improved nutrition and family resource management; and

6. Integrating scientific knowledge of agricultural production, processing, and marketing into systems that optimize resource management and facilitate transfer of technology to users.

The six objectives describe the aims of ARS science. The words "develop the means for" are important. The ARS is a research agency; farmers and ranchers, action agencies, and the private section will actually achieve the stated objectives. The ARS is not the only agricultural research organization working on these or related objectives. The State Agricultural Experiment Stations and Land-Grant Universities contribute to them. Each State also has a Cooperative Extension Service office, Soil Conservation Service offices, and other organizations to help transfer research findings to users. Other Federal agencies, non-Land-Grant Universities, private foundations, and other institutions conduct research on problems that are important to food and agriculture. Industrial organizations conduct research on farming equipment, crops and livestock, agrichemicals, pharmaceuticals, product improvement, marketing, and nutrition—to name but a few. The ARS Program Plan will ensure that our research complements and supports, rather than duplicates, those other efforts.

All six objectives are essential, and achieving them wholly or in part will help meet the stated goal. Conservation and restoration can ensure that the resource base remains adequate for future generations. Increasing the productivity of our crop plants and livestock should help ensure farmers' margin of profit and provide food and fiber to consumers at reasonable costs. Producing food and fiber crops, however, is not enough; raw materials must be processed and delivered in an efficient and timely manner for ultimate consumption. Through all stages of production, marketing, and consumption, products must be protected against losses from diseases and from insects and other pests. Just as important are the safety, wholesomeness, and quality of the products, especially of the basic foodstuffs. Finally, total management systems must be developed to integrate and optimize the use of all basic resources and production factors to ensure that food and other agricultural necessities will be available.

This ARS Program Plan identifies and explains the main problems that confront the agricultural industry and charts the minimum courses of action that will provide the research needed for solutions to the problems. The current ARS budget of about $450 million annually has approximately the same purchasing power as did the 1966 budget. Clearly, the kinds of numbers of projects that can be undertaken within 1966 budget levels are limited. Hard choices must be made. Seventy percent of the members of the ARS scientific staff are 40 years of age or older. That figure implies that turnover and loss of specialists with experience will be extensive during the next few years. We also face a shortage of young, recently trained engineers, computer scientists, biophysicists, molecular biologists, and other critical specialists in the rapidly evolving disciplines needed to solve the problems of the future. To fulfill the Federal commitment of delivering the science and technology that are essential to meet continuing, long-term needs of agriculture, the ARS must maintain a research climate that attracts and retains the best scientists and creative thinkers.

In the past, especially during times of surpluses, various people have argued that production research should be stopped, or at least deemphasized. Conversely, during emergencies or times of shortages, researchers are asked to supply immediate solutions. Research cannot be turned on and off like a water faucet. Stability and long-term commitments are required. For example, research on Marek's disease of poultry caused by a tumor virus was initiated in 1939. The causative virus was not isolated until 1967, and a vaccine was licensed for national use in 1971. By 1974 the annual benefit from the vaccine was $180 million, at a total cost of $31 million in public research funds. Many examples of long lead times can be given for other kinds of technologies, as well as high rates of return from use of the technologies.

The ARS Program Strategy

Agricultural science has been characterized as "the mother of sciences" in recognition of its early development and profound influence on both science and society. We have a vast knowledge base for managing resources, producing crops and livestock, and processing and transporting food and fiber. Some scientists and policymakers, however, question whether our agricultural industry can meet long-term national and export needs and whether ARS, as a research agency, can develop the new technology that would be essential for meeting those long-term needs. The design of the ARS Program Strategy provides for building most effectively on our present scientific knowledge base to identify and pursue the most promising research opportunities, thereby promoting the research that produces entirely new knowledge and technologies. We intend to balance the activities of our program across the spectrum of agricultural research; we will identify the most promising research opportunities, both basic and applied, by considering the supporting knowledge base, the probability of success, and the potential impact of success on our efforts to meet future national agricultural needs.

Overall Research Strategies

Strategies for future production of food and fiber must identify the research that has the highest potential for achieving our objectives through alternative courses of action. The limits of productive capacity that are imposed by current technologies and finite natural resources are real, and they probably will become constraining as they are surpassed by demand. We must conserve our natural resources for future generations. The possibility of substantially increasing food supplies is based on the assumption that we can develop totally new technologies that might increase the efficiency with which plants use the sun's energy to convert soil nutrients, fertilizer, and water into food for humans. In some biotechnological approaches, plants would be replaced by another means of synthesizing food. We may need such revolutionary technologies if we are to reduce the amount of natural resources used in producing food and fiber. Equally important will be the development of improved technologies to augment existing systems for production of plants and animals. Development of revolutionary technologies will take time, and we should get started, but we must temper our optimism about revolutionary technologies. So far we have produced very few, and we must not risk diversion of all our effort from tested and proved research approaches. While we explore new technologies that might rescue us from our dependence on nonrenewable resources, we must intensify our efforts to maintain and improve the productive capability of our agricultural systems.

We need to help farmers and ranchers escape their current economic dilemma—net incomes that are comparable to those of the 1930's. Those independent entrepreneurs, the primary producers of food and fiber, must have an economic environment in which they realize sufficient return, and—thereby—incentive, to incorporate new methods and technologies into their production practices. Only farmers and ranchers who are financially strong can afford the risk of testing new methods in their operations. No national agricultural strategy will succeed unless farmers realize profit. The information produced by research can help not only to reduce production costs, but also to improve economic and political decisions related to agriculture.

Three broad strategies thus emerge for ensuring national security in terms of the quantity and quality of future food and fiber supplies. Those three strategies are represented at different points in each of the six objectives. They are—

- Develop knowledge of and technology for conserving and protecting our endowment of basic resources such as germplasm, soil, and water.

- Develop knowledge of and technology for exploiting known production potentials by closing the gap between average and record yields, reducing losses, and improving the efficiency of current production and marketing systems.

- Develop totally new technologies for producing, processing, and marketing the vast quantities of food, fiber, and other agricultural products that will be needed in the next century and beyond.

The Program Strategy is based on science. The ideas and recommendations of approximately 500 ARS scientists and members of the NPS are summarized in the objectives presented and discussed on the following pages. Research approaches and approach elements that outline the scientific efforts needed to achieve the ARS goal are presented in each objective. The approaches and elements define research strategies and do not necessarily represent current or planned operating programs. Individual programs are, and will continue to be, organized in a manner that facilitates effective management and use of resources. The flexibility to mobilize resources quickly to take advantage of new research findings is of paramount importance.

The Program Strategy describes the minimum number of scientific approaches needed to accomplish the goal. However, all approaches or approach elements may not be given equal support. Priorities will be set by the Deputy Administrator of ARS after he weighs the availability of resources, needs of agriculture, scientific progress, and other criteria. The Administrator will ensure that the priorities are consistent with the goals of the Department. The highest priority portions of the Program Strategy will be included in the Six-Year Implementation Plan for execution by line managers and scientists. In this manner, ARS will help ensure that the best possible science is available to support agriculture. At all times, the ARS will coordinate its efforts with the State Agricultural Experiment Stations, industry, and others who conduct research on these or similar objectives to help ensure that the efforts are complementary. Meeting the research needs of action agencies and policy groups within USDA will have high priority within all six objectives.

Objective 1
Develop the Means for Managing and Conserving the Nation's Soil and Water Resources for a Stable and Productive Agriculture

Natural resources are the foundation of agricultural productivity. The United States has an abundance of productive soil, water, and related air and climatic resources, but the rate of increase in agricultural productivity apparently is declining. Several causes for that decline are related to the quantity and quality of our natural resources. Erosion, a major problem on nearly one-third of our Nation's croplands, not only destroys inherent soil fertility and productivity, but also pollutes water supplies and fills reservoirs and lakes with sediments that are laden with chemicals and nutrients. Of our rangeland, 60 percent is in only poor to fair condition and produces less than half its potential. Ground-water supplies are being depleted in large areas of the Southern Plains and the Southwest. Increased salinity results in costs to both agriculture and municipalities; in the Colorado River basin alone, damages were estimated at $53 million in the 1973 but are expected to reach $150 million annually by the year 2000 unless salt loading can be controlled. Flood damage to downstream property, estimated at $3.4 billion in 1975, is also increasing. Evidence indicates that air pollution reduces productivity more than previously suspected, and damage in the Ohio Valley alone is projected at $8.3 billion by the year 2000. About 3 million acres of farmlands, nearly one-third of which is prime land, is diverted to nonagricultural uses each year. Water, too, is diverted from agricultural to urban and industrial uses, and competition for water is increasing.

We have recovered some of the productivity lost because of damage to our natural resources in the past by investing capital in conservation practices and irrigation and drainage systems and by applying new agricultural technology. Millions of acres of croplands have been improved or reclaimed by the use of lime and fertilizers, soil conservation, and improved water management. Those same technologies, however, along with improved crop varieties and pest control, tend to mask the continuing degradation of

our soil, water, and air resources. Eventually, those technologies will not compensate adequately for the losses in productivity that result from resource degradation, either because of physical limitations—such as decreasing soil depth—or because of economic limitations caused by the high costs of fertilizer, fuel, and other inputs.

Recent resource assessments by USDA, Congress, and others indicate that the United States is reaching the limit of additional land and water supplies that can be developed economically. Among the factors limiting that development are the high cost of energy, high interest rates, and climatic and soil constraints. Available irrigation water will decrease in several Western States because of ground-water mining and increased competition from nonagricultural users. Because plants lose such large amounts of water during photosynthesis, agriculture cannot compete with other industries. Agriculture requires roughly 100 times as much water to produce products of a given value as does the nonagricultural sector. Moreover, much of the additional land available for croplands, about 130 million acres, is fragile and highly susceptible to erosion or already produces forage and timber. Most of the sustainable future increases in production must, therefore, depend not on an expanding acreage, but—rather—on protecting, restoring, or improving soil productivity, improving crop and forage yields, and using existing water supplies more efficiently.

We must develop and adopt innovative and improved approaches to the evaluation and use of resources and to other factors that are critical to productivity if we are to sustain, much less to increase, the agricultural productivity of our resources. Research findings for use by farmers and ranchers, Extension personnel, private industry, action agencies such as the Soil Conservation Service, and many others are the key to new technology for achieving our goal. The research priorities for the Nation that recently were identified by about 100 of the Nation's leading conservationists emphasize long-term national needs, particularly research concerned with the care and maintenance of our soil and water resources. To meet those research priorities, we must increase our commitment to basic research to restock our storehouse of fundamental knowledge.

Approach 1.1 **Develop the Technology for Assessing and Predicting Long-Term Changes in the Quantity and Quality of Soil, Water, and Air Resources Available to Agriculture.**

Approach Elements

1.1.1 *Develop improved techniques and systems for assessing, predicting, and monitoring changes in the productive capacity of land and soil resources.*

1.1.2 *Develop improved techniques for assessing and predicting water supplies and their quality.*

1.1.3 *Develop improved techniques for assessing and predicting the effects of weather and air quality on agricultural productivity.*

18

57-279 O - 87 - 35

Our future food-production systems depend upon continuing supplies of fertile soil, good-quality water, clean air, and a favorable climate for plant and animal growth. The supply of natural resources available to the United States for plant and animal growth is finite, and we must take steps now to provide for continued availability and sustained productivity of those resources for future generations.

We urgently need improved technology for assessing our present land resource base and for defining its inherent productive capacity as the basis for development of optimum conservation practices and sound national policies on the management of croplands and rangelands. The United States has about 10,000 kinds of soil that differ in their physical, chemical, and biological properties and in their responses to cultural inputs. Perfecting and using new techniques, such as remote sensing and computerized data collection, to measure those properties and assess their importance can speed information flow and reduce costs. The current system of soil classification provides data and an initial framework for developing the systems needed for measuring and comparing the effects of different management practices on erosion and productivity for diverse soils, climates, and topographies.

We also need improved technology for assessing changes in the quantity and quality of water resources. As the competition for water grows, accurate and timely information about changes will be vital for making the best use of that resource, which generally is the most limiting factor in agriculture. Only one of many examples is the need to assess the effectivenss of action programs for reducing salt loading in the Colorado River. Better management of our water resources requires improved technology for determining the spatial and temporal distributions of precipitation and for evaluating their effects on the quantity and quality of surface and ground-water supplies. Except in areas with large ground-water supplies, climatic factors largely determine water supply for agricultural production. Variations in weather from year to year modify crop productivity, but long-term climatic differences among physiographic regions are largely responsible for regional differences in soil productivity. Technology for accurately assessing the effects of weather on croplands and rangelands must be improved so that conservation and production strategies at farm, State, and national levels can be optimized.

Recent research has shown that some air pollutants, such as ozone, always reduce crop yields. Sulfur dioxide may either decrease or increase yields and soil productivity, depending upon its concentration in the air and the buffering capacity and nutrient status of soils. Increases in carbon dioxide consistently increase crop yields in greenhouse and growth chambers. We need technology for assessing the long-term effects of projected changes in the concentration of those atmospheric constituents on crop and soil productivity.

Improved technology, such as remote sensing, also is needed for monitoring changes in land use, soil and crop status, and soil- and crop-management practices and for assessing their effects on overall productivity. Improved technology will enable more accurate predictions of national and global production of key agricultural commodities and provide early warning of commodity shortages. Those predictions, in turn, will permit better management of our resources, provide useful marketing information, and aid in the development of sound production and marketing policies.

Approach 1.2

Provide the Technology Needed for Improving, Protecting, and Restoring the Productive Capacity of Agricultural Soils.

Approach Elements

1.2.1 *Develop cost-effective conservation technologies for controlling soil loss from croplands and rangelands.*

1.2.2 *Devise methods for maintaining and improving soil fertility and the chemical and biological properties of soils for optimum crop production.*

1.2.3 *Devise techniques for improving, maintaining, or restoring the physical conditions of soils that are needed for optimum crop production.*

1.2.4 *Devise methods for safety and efficiently recycling municipal and agricultural wastes through croplands.*

Soils, the reservoirs that store the water and plant nutrients that are needed for crop production, also provide the chemical, physical, and biological environment for seed germination, plant establishment, and root growth. Because erosion of soil impairs those functions, we need a fundamental understanding of the physical processes by which wind and water erode soil. We need an integrated research program as a basis for developing highly efficient, cost-effective systems of tillage and conservation practices for control of wind and water erosion. Those systems must be tailored to the specific requirements of each of the many combinations of soils, crops, and climatic zones in the United States.

We must also improve the practices for restoring the fertility of eroded, mined, and marginal lands, as well as for maintaining the fertility of prime agricultural lands. We should direct substantial research effort toward the management of fertilizers. Increasing the efficiency of nitrogen fertilizer from 50 to at least 75 percent would help reduce the impact of the escalating costs of agricultural chemicals on farm income. Enhancement of nutrient availability in soil, of nutrient cycling from agricultural and other wastes, and of the biological environment in soil also could improve fertilizer-use efficiency. Biological nitrogen fixation can reduce the need for fertilizer nitrogen in some cropping systems. To ameliorate the negative effects that adverse chemical and biological conditions in soil have on the productivity and nutritional quality of plants, we need a better understanding of how minerals, including toxic elements, move from soils into plants. We also need to study how pesticides affect the biological properties of soils and their ability to cycle and release plant nutrients. Large quantities of crop residues adversely affect plant growth by releasing phytotoxic compounds during decomposition; those reactions must be understood for effectively managing minimum- and no-till systems. The development of basic knowledge of soil-plant relationships is one key to future technology for improving soil productivity and eliminating barriers that limit crop yields.

Adverse soil conditions such as low water-holding capacity and permeability, compaction, low temperature, and deficient aeration often limit production. Such conditions could be corrected by improved soil-management systems, including conservation tillage and crop-residue management. However, we need basic studies on the causes of poor

soil conditions and on machine-soil dynamics as a basis for defining optimum conditions for the root zone and for designing practices that will ameliorate adverse soil conditions. We also need to better understand soil microbiology and chemistry so that we can specify safe and efficient practices for recycling municipal and agricultural wastes through croplands. Properly used, those wastes could enhance the productive capacity of soils. The recycling of wastes could salvage valuable water and nutrients and provide organic matter to improve the chemical, physical, and biological properties of soils.

Approach 1.3 **Develop Improved Water-Management Systems and Practices To Achieve Effective and Efficient Use of Water Resources.**

Approach Elements

1.3.1 *Optimize the use of water by plants in irrigated and nonirrigated croplands and rangelands to improve and stabilize productivity.*

1.3.2 *Develop methods for increasing, conserving, and managing water supplies available for agriculture, for improving water quality, and for reducing cropland damage from flooding.*

1.3.3 *Improve technology for storing and distributing water supplies efficiently and for improving irrigation, drainage, and salinity-control systems and practices.*

Water is a key resource for agricultural production, and crop yields are reduced more frequently and severely by water stress than by any other environmental factor. Of about 800 million acre-feet of water that evaporates from U.S. croplands each year, precipitation supplies 700 million acre-feet and irrigation supplies 100 million acre-feet. About 20 million acre-feet of the water used for irrigation is from ground-water reserves, and about 70 percent of that water is drawn from the Ogallala aquifer in the Southern Great Plains, which now supports about 20 percent of the U.S. crops that are exported. Large amounts of water are used by nonagricultural trees and plants, lost by evaporation from lakes and reservoirs, or discharged into the ocean in water-short areas of the arid Southwest. For example, phreatophytes, such as salt cedar, consume an estimated 25 million acre-feet of water annually, of which two-thirds could be conserved for agricultural use. Annual evaporative losses from lakes and reservoirs in the arid West total more than 16 million acre-feet. Several million acre-feet of moderately saline water that could be used for producing salt-tolerant crops is now discharged to salt sinks or to the ocean each year. In the future, we will need to manage water much more efficiently than we do now.

The development of technology for increasing water-use efficiency of crops and ranges (production per unit of water consumed) by 25 to 50 percent during the next two decades requires an integrated program of fundamental and applied research directed toward a better understanding of the response of both irrigated and nonirrigated crops to water stress at various growth stages. Also needed is improved technology for increasing storage of rainfall and snowmelt in soils through such means as controlling runoff, increasing infiltration, and reducing evaporation. Such technology is crucial for high production of rangelands and of dryland crops. By using available water supplies more

efficiently on croplands and rangelands, we can increase total crop and livestock production, reduce the year-to-year variations in yield caused by droughts, and reduce production costs on irrigated lands.

The quantity and quality of water supplies for irrigation and other uses depend upon the management of complex watershed systems. We need to develop an integrated research program on effectively managing and, in some cases, increasing the yield of water from croplands and rangelands by improved management of snow and vegetation. We also need to develop improved low-cost structures and practices for control of flooding, ground-water recharge, water quality, and reservoir sedimentation. We need improved technology for economical water harvesting and runoff farming in arid areas. Particularly needed is improved technology for predicting—for major physiographic areas—the effects of land use and land treatment on water yield and quality, ground-water recharge, base flow, and the frequency and severity of flooding.

Of the water diverted for irrigation, nearly 26 million acre-feet is lost annually by seepage in conveyance systems and a similar amount is lost to deep percolation and surface runoff. Some of that water is recovered for reuse in irrigated valleys, but most of the loss from irrigated areas that are adjacent to oceans, inland seas, and salt sinks is permanent. Essentially, all deep percolation from excess water applied on irrigated lands that are underlain by deep, dry sediments is unavailable for future use. We need to develop low-cost methods for controlling seepage and improving the efficiency of water-distribution systems. We also need improved systems and operating criteria that will enable project managers to deliver, and farmers to use, precisely the right amount of water at the right time.

Improved drainage technologies are also needed to avoid overdrainage of coarse-textured soils, minimize crop stress caused by excess water, improve trafficability, prevent salinization of irrigated soils, and increase the production potential of cold, wet soils. Declines of investments in cropland drainage in recent years could be a significant cause of reduced soil produtivity.

Approach 1.4 **Develop Subsystems and Models That Integrate the Use of Soil, Water, and Air Resources for Optimum Management of Major Land Resource Areas.**

Approach Elements

1.4.1 *Develop systems and models for designing resource management strategies that optimize agricultural production and resource conservation.*

1.4.2 *Develop systems and models for designing resource management strategies that will satisfy the needs of nonagricultural resource uses.*

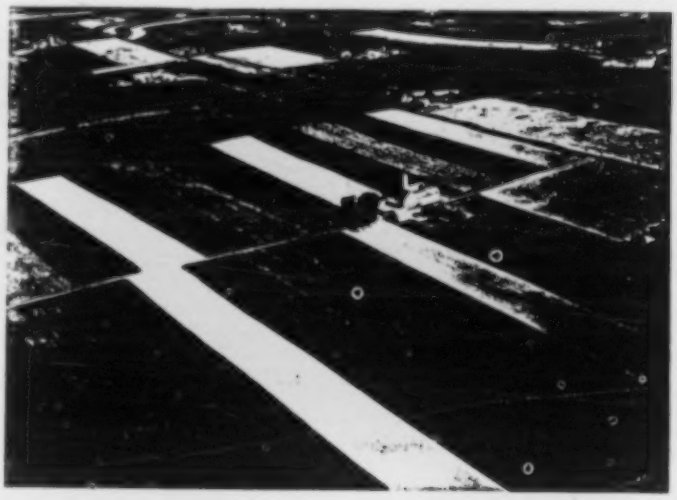
1.4.3 *Develop systems and models for designing resource management strategies that are compatible with environmental quality goals.*

Objective 6 describes user-oriented systems and models that optimize the management of land, germplasm, energy, and other resources for efficient and effective production. Models and subsystems should be developed for the simulation of alternative ways to manage each of the variables. Because the soil, water, and atmospheric components of the agricultural system are so intimately intertwined, the management of one component without influencing or considering the influence of the other components is practically impossible. For example, water and air occupy the airspace within soil in reciprocal proportions; the wetter the soil, the less air it contains, and vice versa. The water content of soil has a major influence on soil temperature.

Some plant nutrients remain dissolved in the soil water and, therefore, move with it. Other nutrients, as well as most organic pesticides and heavy-metal contaminants, are strongly adsorbed on the surfaces of soil particles and, therefore, move only slowly with the soil water. Because the surfaces of clay particles within the soil carry net electric charges, they participate in important chemical reactions. The chemical and physical properties of soil, along with its contents of water and air, largely determine its biological capacity. Plant roots are the most important biotic systems in soils, but microorganisms are important in fixing nitrogen from the air into a form usable by crops, in recycling nutrients from crop and other residues and, in some instances, in facilitating nutrient uptake by roots. Simulation models can be used in predicting the effects of different management practices and in designing improved practices for producing crops and protecting water quality.

In general, agriculture must adapt to, rather than manage, weather and air quality; soil capacity influences the success of that adaptation. Deep, porous soils that effectively absorb and store rainfall are less vulnerable to drought than are shallow soils. Soil capacity, a primary factor in determining fertilizer requirements and stability of crop production in rain-fed agricultural regions, is reduced by soil erosion. Frequent irrigation and fertilization compensate for reduced capacity of the soil to store water and nutrients, but at a cost. We need to develop new and improved management systems for conserving resources and optimizing their use for the long term. Farmers and ranchers control more of our environment than does any other group of people, and they must have the knowledge and techniques to manage the environment wisely.

Objective 2
Develop the Means for Maintaining and Increasing the Productivity and Quality of Crop Plants



Projected long-term demands for the production of our major crops cannot be met with current yields and, for some crops, could not be met even with the highest experimental yields ever achieved. Meeting those demands is as important and as challenging as providing for national defense, finding new energy supplies, and solving other national problems. We must not only meet our own needs for adequate and nutritious food, but also contribute to the nutritional needs of developing countries until they can grow their own food. Further, sales of food and other agricultural products to industrial nations provide markets for farmers and help balance our foreign trade deficit. We do not know that the projected demands can be met, but, to have the best chance, we must develop strategies for breaking down some fundamental barriers that limit crop productivity. We must also explore possibilities of developing new crops and better methods of controlling the losses from all of our crops.

The foundation of crop productivity is the inherent genetic potential of the plants, themselves. Essentially all the crops we grow and use for food and fiber originated outside the United States. Thus, to ensure a full complement of genetic potential and diversity, and to protect against the kind of vulnerability we experienced with the southern corn leaf blight in 1970, we must have programs for the systematic introduction, evaluation, and development of crop germplasm. As the countries where our crop plants originated develop economically and adopt modern varieties of those plants, folk varieties and wild types are being lost. Once lost, plant germplasm cannot be reconstructed and sources of resistance to disease epidemic or extreme drought could be lost forever. Diverse sources of germplasm also exist for beneficial insects, micro-organisms, and other useful biological materials. Such organisms and materials often hold the key to biological control of pests, and some could supply genes for totally new biotechnologies.

Genetic composition is expressed through its interactions with the environment, including weather, soils, diseases, insects, and many other variables, and many sources of germplasm must be evaluated and screened for use in breeding programs. Then, genes that exhibit desirable traits must be characterized, classified, and preserved. Knowledge of biosystematic or taxonomic relationships within the plant and animal kingdoms is essential for both breeding and pest-control programs. We must make this continuum, from source to end use, of plant genes fully functional and maintain balance to improve productivity, quality, and other desired characteristics of crops. The ARS plays a major role in this continuum and, in a sense, is the steward of the Nation's crop germplasm. A prominent ARS geneticist summarized succinctly, as follows: "When embarking on a voyage into a future as uncertain as ours, we must be sure to take along our seeds."

Anyone who gardens knowns the complexity of growing crops. After selecting the best hybrids or cultivars for their climates, farmers face a multitude of decisions for each crop throughout the growing season. They decide, for example, time of planting, spacing of the rows, depth of planting, and number of seeds per acre. Later, they decide how much and when to fertilize, irrigate, or cultivate. Critical decisions also must be made about harvesting. After harvest and before replanting, they must decide the timing and kind of primary tillage needed to protect the soil and prepare for the next crop. Throughout the year, farmers also must select the materials and methods that will best protect crops against weeds, insects, diseases, and other pests that can rob them of all profits. Nearly all of those activities are interrelated and must be scheduled carefully to produce top yields and quality. One mistake often can make the difference between profit and loss. Finding the best combinations of all those practices for each crop and climatic zone is a formidable research task that requires close coordination and working relationships among scientists in ARS, in State Experiment Stations, and in industry. As the limits of productivity are approached, we must increase our basic and applied research to develop cultural and management practices that will consistently produce high yields. Those practices must also be cost-effective.

In the United States, pests destroy one-third of the potential harvest, or about $35 billion worth of products. Pests are legion and include about 10,000 species of insects, 8,000 fungi, 2,000 weeds, and other assorted organisms. To increase productivity, we must control pests. However, control is complex and costly, and experience indicates that it will become much more difficult as we try to wring higher yields from the land. We often control one pest only to find that another prospers in its ecological niche. Organisms may develop resistance to chemicals. Many pest-resistant crop varieties become obsolete in only 3 to 10 years because the mechanism of resistance is overcome by new strains and biotypes of pests. Just to stay even, researchers must race to develop new varieties and protection technologies. We will need totally new approaches to crop protection if we hope to permanently manage the competition from weeds, diseases, insects, nematodes, and vertebrate pests. As growers adopt new technology and practices, such as minimum tillage, scientists are challenged to develop new methods for control of predators and weeds. When farmers convert from a conventional sequence of practices—crop, cultivate, fallow—to minimum-tillage practices, the land's ecology undergoes ma-

jor changes. Weeds, diseases, and predators that were of no economic significance under conventional practices can become so competitive that traditional practices and plant germplasm will no longer protect yields. Then, scientists must develop new, cost-effective materials and methods to meet the new needs.

We also must try to reduce the costs of pest control that now total about $10 billion per year. Another important concern is the prevention of the potentially adverse environmental effects of both the pests and the methods used to combat them. To deal effectively with those and other concerns, we will test alternative courses of action by computerized systems analysis. For example, we will develop and study subsystems for individual crops and pests and then integrate those subsystems into multiple-crop and multiple-pest systems. Thus, by simulating complex systems, we will be able to predict their biological and physical effects on plants, pests, and the environment and to select the best course of action. Systems analysis will also be needed to identify the barriers, in addition to pests, that limit crop productivity. As an example, such analysis might help us to identify the factor that now limits plants' use of available solar radiation to only 1-2 percent, although the estimated potential is closer to 10 percent.

The need for more emphasis on basis research permeates all aspects of crop productivity. During the past decade, knowledge of and new techniques for manipulating the genetic composition of micro-organisms have advanced dramatically. Those advances strongly suggest that genetic manipulation of higher plants could open the door for totally new kinds of biological materials and technologies. That opportunity must be explored, and exploited if possible, through basic research to determine the ways in which genes code for inheritance, genetic messages are expressed in basic processes, and environment modulates genetic expression. Basic knowledge concerning such factors will be needed if we are to break through the limits on productivity now imposed by pests, finite natural resources, and environmental stresses and are to benefit from the full potential of available germplasm. Examples of possible advances are cereal crops that would provide their own nitrogen through biological nitrogen fixation and plants with a genetic makeup that discourages attack by insects, pathogens, and nematodes.

Approach 2.1 **Broaden the Germplasm Resources of Plants and Beneficial Organisms To Ensure Maximum Genetic Diversity for Improved Productivity.**

Approach Elements

2.1.1 *Develop an understanding of the taxonomic relationships among plants, beneficial organisms, and pests as the basis for research to enhance crop production and protection.*

2.1.2 *Collect, evaluate, preserve, and make accessible new sources of germplasm of plants and other organisms and assess their potential for meeting agricultural and industrial needs.*

2.1.3 *Collect, evaluate, preserve, and distribute germplasm of plants and beneficial organisms and of strains of pests that are valuable in pest-management programs.*

Plant germplasm is the base for productive agriculture. It is the genetic raw material that breeders use to develop new, superior crop varieties that can ensure a stable, plentiful supply of high-quality food, feed, and fiber. Only a broad base of plant germplasm can provide the genetic diversity that farmers and public and private plant scientists need to improve the quality and productivity of crops and to minimize their vulnerability to biological and environmental stresses. Crops become vulnerable when stresses from diseases, insects, drought, or temperature extremes exceed the crops' ranges of tolerance or resistance to such factors. The results can vary from localized yield reduction to disastrous crop failures over large areas. Protection from crop losses through control of biological and environmental stresses is far more difficult and costly than is protection through increased genetic diversity among varieties of a given crop. In the former method, we attempt to change the environment to meet the needs of the crop; in the latter, we attempt to change the crop to cope with the environment. We must, therefore, broaden the genetic diversity of crops throughout their production areas by developing—from an array of genetic populations—cultivars that are alike in their productivity, but different in their sources and ranges of tolerance to one or more stresses. Such cultivars could reduce the likelihood of epidemic losses.

An area of special need is a systematic exploration of the plant world for potentially valuable new crops and sources of raw materials for industrial and medical uses. Of the more than 300,000 plant species that nature offers, we now use only about 150 in agriculture. No one knows the potential of most of the neglected plants for tolerance to environmental extremes or for producing needed oils, proteins, gums, waxes, drugs, or other useful materials. The potential of those plants for producing strategic materials and making the United States self-sufficient must be assessed.

Similarly, the world offers a vast resource of diverse germplasm of beneficial parasites, predators, micro-organisms, and nematodes. Judicious introduction of selected species, varieties, and strains of organisms from those sources has led to the control of some pests and a significant reduction in production costs. The use of biological control practices as part of our integrated pest management (IPM) strategy holds great promise for the future.

Taxonomic services and research provide fundamental knowledge for basic research in the protection and production of animals and plants. Taxonomy (or systematics) is essential in the research and development of biological control, IPM, regulatory and quarantine activities, alternative and new crops, genetic selection and manipulation, and industrial uses of micro-organisms. Further, the predictive powers of classifications guide exploration and experimentation in the most promising direction; for example, as in the search for natural enemies of pests or for the origin of genetic diversity of potential new crops. Because agricultural, biological, environmental, and health sciences require prompt input of taxonomic data, and because the classification of the estimated 10 million animal and plant species is far from complete, many taxonomic specialists are

needed. Unique and vast resources (specimen reference collections and extensive published and unpublished information) must be physically maintained. Also, the information must be computerized for rapid delivery to and use by a diverse clientele in the development of new research. For efficient utilization and protection of our flora and fauna, we must have the holistic knowledge of their natural relationships that only a solid program of biosystematic research can provide.

Approach 2.2 **Select and Modify Germplasm of Plants, Beneficial Organisms, and Pests.**

Approach Elements

2.2.1 *Devise new methods for modifying germplasm of plants, beneficial organisms, and pests.*

2.2.2 *Improve genetic populations of range, pasture, forage, and turf.*

2.2.3 *Improve genetic populations of field crops.*

2.2.4 *Improve genetic populations of horticultural and specialty crops.*

2.2.5 *Improve genetic populations of beneficial organisms, and develop inferior strains of pests that will be useful in pest-management programs.*

The procedures for selecting and modifying plants and beneficial organisms are similar, particularly for range, forage, field, horticultural, and specialty crops. For the purposes of these discussions, in objective 2 no effort will be made to address production or protection procedures on a crop-by-crop basis.

Developing crops that are well adapted to their environments and have desirable nutritional or commercial quality is a long and costly process. Many steps are involved—from the most basic genetic research to maintenance of breeder stocks. Decades may be required to incorporate a desired quality into an adapted crop plant. In contrast, a commercial variety or hybrid may last only a few years before succumbing to a disease organism or insect. For those reasons, plant-improvement programs must have stability and continuity and remain vigorous in the foreseeable future.

Once genetic resources have been screened, genes for the desirable traits that are identified must be combined into improved strains that will be useful to breeders and, eventually, to growers. Resistance to pests, tolerance to cold or drought, high protein content, early maturity, and a host of other desirable features are needed for commercial production. However, those traits rarely are found together, and they may be found in stocks that are unsuited for cultivation. In developmental breeding, which ties together the work of germplasm collection, screening, and gentic analysis, scientists sort—from the many objectives or traits that might be pursued—those with a high probability of success.

Candidate strains and varieties are evaluated through replicated performance trials over several years and several locations. For valid assessments, they must be tested with many combinations of soils, nutrient levels, diseases, insects, weather, cultural practices, and harvesting methods. Only by stringent evaluation of candidates can genetic yield potential keep pace with the increasing demands and complexity of crop production and marketing systems. In recent years, especially with advances in genetic engineering, increased emphasis has been placed on finding ways to shorten the process of crop improvement and to make it more efficient and less costly. However, we should recognize that crop-improvement programs, although slow, have been exceedingly successful and form a solid foundation for the whole agricultural industry.

Emphasis on finding biological agents for pest control has increased. The use of parasites, predators, pathogens, and other kinds of agents as a single tactic or as part of an integrated program offers the potential for pest control that would be economical, energy saving, environmentally safe, and—often—permanent. Such technology is in its infancy, however, and we need much additional research to increase the arsenal of natural enemies. Expanded foreign exploration, quarantine research laboratories, and basic ecological studies will be required.

pproach 2.3 **Develop Improved Production Practices for Maintaining and Increasing Crop Productivity and Quality and for Reducing Costs.**

Approach Elements

2.3.1 *Develop knowledge of basic plant growth and development processes of crop species and of micro-organisms of agricultural importance.*

2.3.2 *Develop basic ecological principles and improved cultural and management practices for range, pasture, and forage.*

2.3.3 *Develop basic ecological principles and improved cultural and management practices for field crops.*

2.3.4 *Develop basic ecological principles and improved cultural and management practices for horticultural and specialty crops.*

2.3.5 *Develop basic principles for and improved methods of pollination and honey production.*

2.3.6 *Discover principles for and develop criteria and specifications for improving the efficiency of agricultural production and protection equipment and practices.*

Production research is the essential step through which basic knowledge and germplasm resources become useful on the farm. In the production phases of agriculture, genetically controlled biochemical and biophysical processes are expressed as leaves, flowers, or fruit in the conversion of solar energy, soil, air, and water into food and fiber. The purpose of crop-production research is to identify major cultural problems and limitations and to develop practices that solve or circumvent them. Such research requires

knowledge of the basic plant processes that are responsible for the growth and development of plants, as well as close coordination among plant breeders, engineers, entomologist, pathologists, soil scientists, and others. This research is concerned with all aspects of production—from the planting of viable seeds to seedling establishment, plant flowering, and harvesting of vegetative portions, seed, or other crop products. Both quantity and quality are important. For some crops, pollination by bees or other insects is essential, and honey is a valuable byproduct of pollination.

Production research must deal with many variables, most of which interact. Some of the major variables are tillage practices, crop varieties, row widths and planting density, time of planting, fertilization and irrigation (both timing and amount), pest-control methods and practices, time and methods of harvesting or grazing, and—most influential of all—the weather. Many cultural practices are used even for a single crop in the United States, and finding the best one(s) is an enormous task. Quality, especially in food crops, is often as important as is quantity of production. The payoffs, however, are high. Cash receipts totaled nearly $70 billion for the crops produced in 1980, despite losses of about $20 billion caused by one of the worst droughts we ever experienced. However, losses would have been much greater without the production technologies and superior germplasm developed through research.

To meet projected demands for crops and to reduce the costs of producing them, we will need to expand production research. As new crop varieties and hybrids become available, the best combination of practices must be found. A particular opportunity for the southern half of the United States is the use of double cropping to take advantage of the long growing season and high rainfall in the Southeast. Major research needs are the development of cultural practices for safe use of erosive and other marginal lands and the restoration of the 60 percent of our rangelands that is in poor to fair condition. In that research, consideration must be given to many kinds of equipment—planters, cultivators, sprayers, fertilizer spreaders, harvesters, and primary tillage machinery. As farming becomes more complex and precise, so do the machinery and practices for delivering needed inputs at the proper times, rates, and combinations. Researchers must help determine design criteria and specifications so manufacturers can produce better equipment for agricultural production and protection, and farmers can reduce their production costs.

Approach 2.4 **Discover Principles and Develop Improved Methods for Reducing Crop Losses Caused by Weeds, Diseases, Insects, Nematodes, and Other Pests.**

Approach Elements

2.4.1 *Develop knowledge of growth, development, and behavioral and population processes of insects as a basis for discovering control principles.*

2.4.2 *Develop knowledge of etiology, epidemiology, and pathogenicity of plant pathogens as a basis for discovering control principles.*

2.4.3 *Develop knowledge of growth, development, and behavioral processes of nematodes as a basis for providing control technology.*

2.4.4 *Provide technology for protecting range, pasture, forage, and turf from losses caused by insects, nematodes, pathogens, and other pests.*

2.4.5 *Develop principles for protecting field and horticultural crops from losses caused by insects, nematodes, and pathogens.*

2.4.6 *Develop knowledge of the basic biology of weeds determining their vulnerability to control.*

2.4.7 *Develop control technology for reducing losses caused by weeds in forage crops, pastures, rangelands, turf, aquatic environments, and noncroplands.*

2.4.8 *Develop control technology for reducing losses caused by weeds in field and horticultural crops.*

2.4.9 *Develop fundamental principles of biological control for pests of crop plants.*

2.4.10 *Discover principles and develop agricultural chemical technology for reducing crop losses and for modifying plant growth for improved crop protection and production.*

2.4.11 *Develop fundamental principles for the control of vertebrate pests.*

Crop losses caused by pests of various kinds are estimated at $30 to $40 billion per year, plus another $10 billion spent in efforts to control them. Roughly 10 percent of those pests are perennial problems of economic significance. Experience suggests that the difficulty of protecting crops increases as production practices become more sophisticated and intensive. An example is the serious weed problem now appearing in minimum-tillage and "no-till" systems. We can expect many kinds of pest problems in double-cropping systems, especially those coupled with tillage methods that leave crop residues on the soil surface. Unless we can markedly improve our understanding of the growth, development, and behavior of pests, opportunities for major improvements in crop productivity and erosion control will be severely limited.

The magnitude and complexity of the task facing researchers and action agencies are illustrated by the large numbers of pest species of economic significance. Consider, also, that some pests attack several crops—or one crop may be attacked by several pests—and that the soils and weather, along with fertilization and other cultural practices that control the growth and interactions of the pests and crops, have many variables. Those variables and the ability of pests to adapt rapidly to changes in their environment explain the short utility—possibly only 10 years or less—of control practices or resistant crops. The research task is not only complex, but also apparently never ending.

To gain some control over pests, we need research programs with the highest degree of innovation and sophistication. The programs must extend from the most basic studies at the cellular and molecular levels to large-scale pilot studies in the field. We must find better ways to follow the life cycles and migration patterns of pests, to mathematically

describe their growth and development as functions of temperature and other key variables, and to monitor and assess population increases and damages. Then we can develop improved technologies—both chemical and biological—that will interrupt the growth of pests at strategic times and prevent their buildup to economically damaging levels. Such technologies must be developed for each crop and each pest. No one practice or management system can suffice, although IPM systems hold great promise for some combinations of crops and pests.

Vertebrate predation causes large losses to agricultural products—both before and after harvest—in the United States and abroad. Continued research effort must address those losses. Coyotes and birds—along with rats and many other rodents—soil, kill, consume, or devalue products or increase operating costs at many levels of the agricultural production, distribution, and marketing systems. Efficient, safe, economic controls must be devised. Through research, new technology will be made available.

Scientists think that research has a high probability of success, not only for cutting crop losses, but also for reducing control costs and for preventing potentially adverse side effects from pesticides. Certainly the potential benefits are great—$11 billion annually for improved weed-control measures alone. Research on the control of crop pests also has significant indirect benefits in protecting people and animals from insects and the diseases they carry, from allergenic and toxic plants, and from other pests. Also important is the support that the research provides for the action programs of several agencies, most notably the Animal and Plant Health Inspection Service (APHIS) of USDA.

Approach 2.5 **Develop Improved Methods for Integrating the Crop- and Pest-Management Practices Needed for Higher and More Stable Levels of Crop Production.**

Approach Elements

2.5.1 *Develop the means for assessing crop conditions, and identify the factors that limit yields of major crop commodities.*

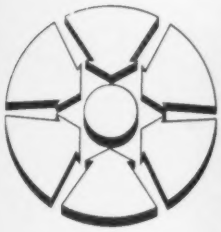
2.5.2 *Develop growth and management models for optimum production of crop commodities.*

Crop production is one of our most complicated activities. Most industrial commodities are produced in factories with controls and checks at every step. In sharp contrast are the farms with no control over such main variables of production as sunlight, rainfall, temperature, and wind and only limited control over many of the pests that limit production. Knowledge is the key to dealing with such uncertainty and risk. With precise knowledge of the way crops and pests grow and interact with each other and the environment, we can identify limiting factors. We can also build predictive models to help farmers respond to pests or adverse weather with management practices that will conserve inputs and maximize farm profits.

In this approach, the data from the basic and applied research described in the other approaches in objective 2 are incorporated into subsystems and simulation models that are useful to both researchers and producers. Those subsystems also serve as components of the complete agricultural systems described in objective 6. As one example of the need for such systems research, no one knows why average farm yields of several crops peaked years ago or has identified the barriers that limit further increases. To find the reasons and identify the barriers, we need to measure and analyze the relationships of crops and pests to each other and to environmental factors such as light intensity, humidity, temperature, soil fertility, and soil moisture. As one author stated recently, "Only to the extent that we can describe productivity in terms of the mechanisms that control photosynthesis and growth can we bring productivity improvement out of the dark ages of pure empericism."

Simple, quantitative models that incorporate data from broad agricultural and economic sources are becoming powerful farm-management tools for optimizing production. They can be used to determine optimum rates of fertilization, times for spraying insects, and times for and amount of irrigation, as well as to guide managers in other critical decisions. Models also can be used to help identify research opportunities and critical field experiments that are needed for each combination of pest and crop. The key in this approach is the integration of our knowledge of crop plants and of the pests that limit their productivity. New and improved IPM systems are especially needed for optimum control of pests of all the major crops.

Objective 3
Develop the Means for Increasing the Productivity of Animals and the Quality of Animal Products



The availability of a vast array of foods from animals helps make Americans among the best fed people people in the world. Because animals convert plant materials that humans cannot digest to foods of high nutritional quality and monetary value, they are an important link in the food chain. Opinions differ among scientists about the proportion of our diet that should come from animals sources. Of diets consumed by Americans, however, more than 45 percent (by weight) is derived from animals. Animal products supply two-thirds of the protein, one-third of the energy, four-fifths of the calcium, and nearly two-thirds of the phosphorus in the American diet. Foods from animals also are major sources of vitamin B_{12} and important sources of iron, vitamin A, thiamine, riboflavin, vitamin B_6, and other essential minerals, micronutrients, and vitamins. As developing countries improve their economies and as U.S. citizens move up the economic ladder, their demand for foods from animals tends to increase. Animals also provide leather, wool, feathers, horn, bone, and biological products, such as the hormone insulin, that are important to human health. Animals are important models for conducting research related to the improvement of human health, are still used in some areas for transportation and power, and provide pleasure for many people. Beef and dairy cattle, swine, sheep, goats, poultry, horses, fish, rabbits, fur-bearing animals, laboratory animals, some beneficial and harmful insects, and predators and other specialized animals that are related to agriculture must be considered in our research strategy. Aquaculture (fish farming) is an emerging area of opportunity for increased productivity and more efficient use of land and water resources.

Animal production is important to the U.S. economy and generates about 52 percent ($70 billion in 1980) of the total farm income. Grazing animals are important in the use and maintenance of the natural resources in our ranges, pastures, and forests. They con-

tribute to resource conservation by producing food from land that is not made vulnerable to erosion by tillage and from land in terrain that is unsuitable for crop production.

Losses from diseases, parasites, pests, and biological and management inefficiencies cause losses to the animal-production industry and to consumers that amount to billions of dollars annually. Research must generate the necessary knowledge and technology for reducing those losses and for supporting action and regulatory agencies of the USDA and other Federal departments in carrying out their responsibilities. Through a combination of research, development, and education, the efficiency of many phases of animal production has increased substantially in the last 20 years. However, as described for crop production, we have reached the limits in many instances, and further progress requires research ranging from fundamental studies of intricate life processes to the development of totally new ways to increase efficiency and productivity. Inadequate basic knowledge is the major limiting factor in improving the efficiency with which we produce and utilize foods and other products from animals. In a conference in May 1980, more than 200 leading scientists, producers, industrialists, consumers, and experts in human nutrition and medicine identified research needs that, if satisfied, would enable agriculture to effectively and efficiently meet future demands for animal products. The approaches and elements listed below are consistent with the priorities identified at that conference.

Approach 3.1 **Increase the Genetic Capacity of Animals for Production.**

Approach Elements

3.1.1 *Devise optimum selection and mating procedures for obtaining high levels of animal performance and improved product quality.*

3.1.2 *Devise procedures for selectively manipulating genetic material to improve desired characteristics.*

3.1.3 *Determine genetic variation in biochemical, physiological, and behavioral traits of animals, and devise ways for using the information to accelerate genetic improvement.*

3.1.4 *Improve genetic resistance of animals to diseases and internal and external parasites.*

The productivity of farm and range animals is shaped by both their genetic makeup and their environment. Much of the improvement in animal productivity in recent decades has resulted from increased genetic capacity for synthesis of meat, milk, eggs, wool, and other animal products. To genetically improve animals, breeders must identify animals that are genetically superior for given environments. The long gestation, slow rate of maturation, and low prolificacy of large farm animals lengthen the time required for evaluating animal performance. To accelerate progress and reduce production costs, we must establish procedures for identifying animals that are genetically superior without waiting for their full development. Such procedures will require new methods for reliably estimating both the genetic merit of individual animals and the performance of specific matings for the development of alternative systems for selecting and mating animals.

Genetic engineering research could produce techniques for identifying and transferring genetic material between animals and between animals and bacteria. Possibly through cloning and related technologies, genetic copies of superior animals could be produced. Other long-term research is needed on genetic manipulation to produce animals that are resistant to diseases and parasites. If we could identify the genes and their products that make certain animals susceptible or resistant to parasites and diseases, resistance might be bred into livestock

We must determine, in animals, the effects of genetic variations on hormones, enzymes, and other biochemical regulators of performance and of economically important traits. The genetic control of immune responses, behavior, and resistance to diseases, parasites, pests, and other stresses also must be studied. Of particular importance are genetic influences on metabolism that might be used to regulate the types and proportions of fats, proteins, vitamins, and minerals in animals and in foods produced from them.

Approach 3.2 **Improve the Efficiency of Reproduction and Reproduction-Related Biological Processes.**

Approach Elements

3.2.1 *Increase the number of offspring reared per male and female maintained.*

3.2.2 *Increase efficiency of germ cell and embryo production, transfer, and storage and of techniques for producing more offspring of superior quality.*

3.2.3 *Increase efficiency and persistence of lactation and egg production.*

The failure of animals to reproduce consistently and prolifically is one of the most costly and production-limiting problems facing our livestock industries. Annual losses from low performance are estimated at $10 to $14 billion, or 14 to 20 percent of the total income from U.S. animal agriculture. The reproductive rate of most animals is 80 percent. A 10-percent increase in reproductive rate would increase efficiency by 6 percent, which alone would save producers about $4 billion annually.

Reproductive efficiency might be improved by increasing twinning in beef cattle, shortening the calving interval in dairy cattle, increasing embryonic survival in swine, and increasing the frequency of multiple births in sheep. We should develop and improve procedures for controlling the timing of ovulation and for synchronizing estrus. Nuclear transfer, semen preservation and predetermination for sex, *in vitro* fertilization, and mechanisms for controlling the fertility characteristics of individual animals also should be emphasized. We must undertake basic biological research on development of the technology for freezing, storing, and then thawing embryos for use in improved technologies for transferring embryos. The answers gained through basic and applied research in all of those areas, and their subsequent use by producers, could significantly advance the genetic and productive capabilities of livestock.

We need a better understanding of the endocrine and neuroendocrine mechanisms that regulate feed-energy conversion and milk-secretion processes and of the hormonal and cellular mechanisms that control milk synthesis. To improve the productive capacity of

turkeys and other poultry, we need similar studies to determine the mechanisms that regulate egg synthesis. Studies are also needed on turkey-semen preservation, sperm transport, ovulation, and oviposition and on their relationship to egg hatchability.

A strong, integrated research program to improve the reproductive efficiency of animals is essential for maintaining progress in the efficient production of meat, milk, eggs, and other animal products.

Approach 3.3 **Improve Animal Nutrition and Feed Efficiency To Increase Productivity and Product Quality.**

Approach Elements

3.3.1 *Remove nutrient limitations to production.*

3.3.2 *Reduce losses and inefficiencies in nutrient use, and explore alternative sources of nutrients.*

3.3.3 *Devise nutritional and physiological means for modifying the rate of synthesis and the composition of animal products.*

Because feeds represent 40 to 50 percent of the total costs in animal production, efficient feed utilization is essential for profitable production of meat, milk, and eggs. We must improve our understanding of the factors that affect nutrient needs; the digestion, absorption, and assimilation of nutrients; and the synthesis of animal products. Any gains made in improving feed utilization by animals and in lowering feed costs will improve the economic viability of livestock producers and lower the cost, to consumers, of foods from animals.

Only through basic research can we understand the metabolic processes through which animals convert feed to meat, milk, and eggs and, through that understanding, develop technology that will enable animal producers to improve the efficiency of the metabolic processes that control the composition of animal products. Although general nutrient needs of animals are known, we now need to know their specific nutrient needs, at various stages of their life cycles, for producing meat, milk, eggs, and wool of the highest quality and in the greatest quantity. As we genetically improve the productivity of animals on farms and rangelands, we must reconsider their nutrient requirements. Maximum animal performance depends upon high feed intake, and we must define the physiological factors that control the appetite of animals in different stages of growth and under different environmental conditions. The effects, on feed intake, of (1) composition and physical state of the feed and (2) physiological factors should be clarified. By understanding the nutritional needs of animals at all times, we can devise improved ways for managing soils, crops, and livestock to meet those needs.

Microbes in the digestive tracts of animals ferment and grow on feedstuffs consumed by the animals and, in ruminants, are responsible for cellulose digestion. Feedstuffs must, therefore, be designed to nourish both the host animal and the desirable microorganisms in the digestive tract. Because cellulose is a major component of many feeds,

we need to understand the factors that limit digestion of cellulose and hemicellulose and the conditions that favor maximum benefits from the micro-organisms in the gastrointestinal tract. Additional research is also needed on chemical and biological procedures that will free, for use by ruminants, extra energy from the lignocellulosic substances in low-quality feeds, forages, and plant residues.

Approach 3.4

Develop Ways To Prevent or Control Losses From Diseases, Parasites, and Toxicants and Other Substances That Limit Animal Performance and Reduce the Quality of Animal Products.

Approach Elements

3.4.1 *Improve methods for diagnosing and identifying agents that cause losses, and improve methods for assessing those losses.*

3.4.2 *Establish the roles of environmental stresses and nutrition in losses from diseases and parasites.*

3.4.3 *Characterize the mechanisms by which animals become infected and are affected by diseases and parasites.*

3.4.4 *Devise new and improved methods for preventing or reducing death, morbidity, and other losses from diseases and parasites.*

3.4.5 *Prevent, control, or eliminate losses from natural or synthetic substances to which animals may be exposed.*

Throughout the world, diseases, internal parasites, and toxicants cause major losses and are important causes of low animal productivity. In the United States, they cost livestock producers, and subsequently consumers, an estimated 20 percent of the farm income from livestock and poultry products, or about $14 billion per year. Losses from diseases, internal parasites, and toxicants include death, restricted growth, reproductive inefficiencies, and veterinary costs. Other losses are from "production diseases," which often produce no recognizable clinical signs of disease but do lower productive efficiency. As a class, they are complex epidemiologically and have infectious, toxic, genetic, metabolic, and nutritional etiologies, or combinations thereof. They generally result from several etiological factors that act in concert with environmental and production factors. This class of diseases includes infectious complexes, reproductive disorders, metabolic imbalances, toxicoses, digestive system disorders, nutritional disorders, stress-related syndromes, parasite and insect infestations, and combinations of two or more thereof.

Research is needed to find new and improved methods for identifying losses from diseases, parasites, and toxicants. We need tests for diagnosis of recognized diseases, detection of inapparent carriers, identification of new diseases or sources of loss, and assessment of losses attributable to individual diseases. Rapid diagnosis is critical for treating sick animals early, preventing exposure of healthy animals, and safely moving animals from one farm to another. The identification of new diseases should help control losses from "production diseases" and from reproductive diseases, which often are never identified because the disease-causing agent disappears before its effects are seen.

Research is needed to define the effects, on health, of stresses associated with the environment, disease, and nutrition. We should study the factors that influence infection by disease, including the effects of hormones on the immune system and the response of animals to vaccination. We also should study, at the cellular level, the interactions of disease agents and the control of interactions by hormones and genes. Stresses and nutrition also affect losses caused by parasites, but those interactions are poorly understood. Even more poorly understood are the mechanisms by which diseases and parasites are transmitted, infect animals, and adversely affect their health.

Recombinant DNA technology is expected to revolutionize the production of vaccines and other biological materials that are needed to prevent disease or promote growth. Advantages of the technology are safety of the products and the ease with which abundant supplies of vaccines and materials can be produced. We should thoroughly explore the potential of recombinant DNA technology for producing vaccines and products that stimulate the natural immunity of animals.

Research is needed to determine the toxic, metabolic, and subclinical effects of agricultural chemicals and poisonous plants on livestock and the relationships of those chemicals and plants to diseases and efficiency of production. In that research the risks of undesirable residues in meat, milk, and eggs should be assessed. Further research is needed on medicinals, feed-grade chemicals, antimicrobials, and drugs for prevention and control of disease and/or for increasing efficiency of animal production. Research also is needed to identify plants that may be harmful to animals; to determine their toxic components, mode of action, and possible hazards to public health; and to find means for preventing losses of livestock from exposure to such plants.

Approach 3.5 **Develop Means for Controlling Insects, Ticks, and Mites That Affect Animals and Man.**

Approach Elements

3.5.1 *Improve methods of detecting infestations and assessing losses.*

3.5.2 *Examine mechanisms by which insects, ticks, and mites cause harmful effects.*

3.5.3 *Devise new and improved methods for reducing losses from insects, ticks, and mites that affect animals and man.*

3.5.4 *Integrate control technologies into systems approaches for managing insects, ticks, and mites that affect animals and man.*

3.5.5 *Develop means for protecting humans from insects and insect-borne diseases.*

'In the United States, insects, ticks, and mites that affect livestock and poultry cause annual losses estimated at more than $3 billion. Insects, ticks, and mites also directly affect people by impairing their health and productivity through annoyance, debilitation, and disease transmission. The estimated annual cost of those pests and disease vectors to civilian and military populations of the United States exceeds $1 billion.

A balanced program of basic and applied research should provide the knowledge and technologies that are needed to alleviate those losses. Methods of detecting infestations of insects, ticks, and mites must be improved, and thresholds of economic importance must be determined for species that affect man and animals. Early, accurate detection of infestations and assessment of losses are essential to timely application of control measures. Basic research on the biology and ecology of specific pests is needed to provide the knowledge for designing effective controls. For development of vaccines, we must understand the role of immune systems in the natural and acquired resistance of animals and identify the genetic products and immune-response genes that are responsible.

New and improved methods of reducing losses should be emphasized in research on the chemical control of insects, ticks, and mites that affect man and animals. Genetic methods of altering the pests, themselves, also must be devised through such mechanisms as hybrid sterility, male sterilization, cytoplasmic incompatibility, chromosomal translocations, compound chromosomes, and other genetic anomalies. Special attention is needed to discover and develop effective bilogical control agents, such as pathogens, parasites, and predators. Possibly in studies of animal facilities, water management, or manure disposal, we could develop improved techniques for control. Basic research may reveal either physiological systems that can be interrupted to alter pest behavior or ways for producing new, physiologically active chemicals to control pests. Applied research will be used to combine chemical control, host immunity, genetic control, biological control, cultural control, and novel approaches into integrated systems for the management of insect, tick, and mite populations so they can be maintained below thresholds of economic importance.

A strong research program that provides the means for controlling insects, ticks, and mites that affect animals and man should enable farmers, with the help of such agencies as APHIS, to reduce animal production losses by 15 percent (national total of $450 million per year). It should also provide the means, particularly through the Departments of Agriculture, Defense, and Health and Human Services for reducing direct losses to human health and productivity by 20 percent, or $200 million per year. Potential savings in human life, health, productivity, and well-being are inestimable.

Approach 3.6

Devise Means for Improving and Integrating Procedures and Facilities for Production and Transport of Animals To Increase Productivity, Reduce Costs, and Minimize Stresses.

Approach Elements

3.6.1 *Assess environmental impacts and shelter needs for farm animals.*

3.6.2 *Develop facilities and equipment for feedstuff storage, processing, and distribution.*

3.6.3 *Develop facilities and equipment for improving animal performance and labor efficiency in production systems.*

3.6.4 *Develop improved facilities and equipment for handling and transporting animals.*

3.6.5 *Develop systems for managing and using manure efficiently as a resource.*

3.6.6 *Devise integrated management practices for maximizing animal productivity and product quality, while minimizing stress.*

3.6.7 *Evaluate, for optimum use of resources, management programs that integrate all productivity elements under various environmental conditions.*

As labor and other costs have risen, animal producers have improved efficiency through better management and the use of labor-saving equipment, and the average size of animal-production units has increased. Millions of dollars are invested annually in animal-production facilities and equipment. For reduction of those costs, research is needed to provide engineering and management technology for modern livestock and poultry farms and to integrate available technologies into efficient systems.

Environmental factors interact to influence animal performance. We should conduct research to define the criteria that are needed for evaluating environmental requirements for optimum animal performance and for designing more effective facilities and equipment to protect animals from weather, insects, diseases, and other destructive influences. Valid models must be developed for assessing environmental impacts on animals and for selecting alternative shelters and handling procedures and equipment for farms, feedlots, and ranches.

We must find ways to increase the efficiency and accuracy of feed preparation, delivery, and utilization by improving the facilities for storage and handling and the controls for blending and dispensing. Automated procedures for collection and analysis of information should be developed that will facilitate daily management decisions on breeding, feeding, housing, and marketing and on control of diseases, parasites, and pests. We must find ways to reduce the losses of animals and animal products during handling and shipping. Another area of opportunity is finding ways to efficiently use the nutrients and energy contained in animal wastes.

Management systems for optimum use of resources must be evaluated for most efficient production of beef and dairy cattle, swine, sheep, poultry, fish, and other economically important species. All aspects of farm-animal production must be integrated into total management systems that provide optimum care for animals, reduce stresses, and improve efficiency and product quality. Integration will involve development and evaluation of computer simulation models of alternative total management systems for the optimum use of biological, physical, and economic resources under the widely different conditions across the United States. Reducing losses of animals to predators is a critical need in some phases of livestock production.

Objective 4
Develop the Means for Achieving Maximum Use of Agricultural Products for Domestic Markets and Export

Public benefit from agricultural business depends upon delivery of a dependable supply of food and other agricultural products to consumers through an effective and efficient marketing system and upon an adequate return to farmers who produce the raw products. The economic incentive for engaging in agriculture—the planting of crops and the breeding of animals—lies in the increment between the costs of a farmer's total investment and his total return. That increment, profit, depends heavily upon the marketing system. A myriad of firms, organizations, and individuals pack, process, handle, transport, store, and distribute farm products. In fact, marketing costs accounted for more than two-thirds ($183 billion) of the money spent for domestically produced farm foods in 1980.

The difference between the price received by farmers and the price paid by consumers—the "farm-retail price spread"—has been increasing in recent years and undoubtedly reflects the rising costs of capital, labor, services, and all other inputs that are added, during marketing, to the costs of production. Some added costs do increase value by enhancing the safety, nutrient content, or convenience of food items or the utility of nonfood items, but others reflect the costs of advertising and extravagant packaging. The increasing farm-retail price spread also could indicate declining efficiency in the marketing system. We must pursue research that facilitates the profitable marketing of both the raw agricultural materials and the processed products manufactured from them.

No products of American business are more important to the Nation's economic health than are the exports that earn foreign credits. Among our total exports, agricultural products predominate and indirectly help pay for the oil and manufactured products that we import. Maintaining and enhancing the value of those exports could help achieve op-

timum use of our agricultural product. We should also develop new crops and products for export. We must develop technologies, for all phases of posthar[illegible] treatment and for transport, that will ensure delivery of high-quality products to foreign markets. New scientific information about the essential characteristics of agricultural products for export and about the technologies for shipping those products should not only help other Government agencies in establishing standards that meet export goals, but also help industries in developing products and technologies that meet the needs of foreign buyers.

Most agricultural products must be processed or modified in some way before they are marketed and used by consumers. Modifications can range from subtle improvements—for example, removal of green color from oranges— in products that are consumed as harvested to separation into components for direct use or for use in formulations, mixtures, or unique products. The changes may either improve the nutritional, sensory, or functional characteristics of products or improve their safety, durability, convenience, and utility. Conversions of agricultural wastes and residues—and even new crops—into alternative fuels and petrochemical substitutes are examples of processing products into nonfood items. Traditional processing operations include physical, chemical, and biochemical methods. Recent advances in biotechnology open the door for creating totally new kinds of food and nonfood items from agricultural raw materials and for improving the utility of traditional items.

To develop advanced technologies, scientists must first acquire basic knowledge of the chemical and physiological processes and properties of individual commodities and potentially valuable new crops. Certain traits can be used as indexes for objectively and automatically classifying, sorting, and segregating commodities according to their quality, safety, and market value. Those indexes could also be useful as criteria for use by geneticists and breeders in developing genotypes with improved quality.

We often need basic data for improving technologies for preserving and storing agricultural products. The perishability of raw agricultural commodities is a major challenge to the marketing sector and to research. Perishability is manifested in different ways and to different degrees. Each commodity requires specific methods of protection during handling, storing, processing, and retailing to prevent deterioration, loss, or contamination that could be hazardous to consumers. Major factors that influence perishability are damage—from insects, microbes, and physical abuse—and chemical and metabolic breakdown. Those factors cause annual losses of food, alone, estimated at $31 billion. In addition, all the labor, energy, and other resources expended during production and marketing, up to the time of loss, are wasted. To meet future needs for food and fiber at affordable prices, we must find more effective ways to prevent losses.

Scientists also should develop means for enhancing the total market value of the agricultural product. With new technologies, we should be able to increase the marketable portion of the agricultural output, enhance desirable traits, and decrease or eliminate undesirable traits in natural or processed products of plants and animals. We may be able to find new crops or to develop totally new products.

Scientists also are challenged to develop means for improving the overall efficiency of the entire system of harvesting, processing, transporting, and marketing. Inefficiencies in that system could offset potential gains in yield and product quality. We need to identify the costs for labor, time, energy, water, and other inputs that could be reduced and the steps and procedures that could either be eliminated or combined to shorten and simplify the whole marketing process. We need studies of the methods, facilities, and equipment used to handle, process, grade, package, and ship specific commodities and products. In those studies, we should examine the system from the farm through assembly points, processing plants, storage, and delivery. In the analysis of the marketing system, use of computerized information systems and models will help us to identify inefficient steps that should be modified or eliminated.

Approach 4.1 **Develop Means for Enhancing the Inherent Properties and Uses of Agricultural Materials.**

Approach Elements

4.1.1 *Characterize the basic, physical, chemical, and aesthetic properties of plant and animal materials that enhance their usefulness.*

4.1.2 *Identify the biological and biochemical mechanisms, in plants and animals, that affect properties of agricultural materials.*

4.1.3 *Devise means for regulating and controlling the biological processes that enhance usefulness.*

4.1.4 *Devise concepts for innovative and improved processes and products.*

For maximum value, farm products must meet market demands for quality and utility. However, we often cannot measure either trait directly and must characterize its associated properties—such as flavor, color, texture, and strength. We need new chemical, mechanical, or electronic methods for evaluating quality and utility objectively.

The basic biological and biochemical processes that function in the cells of growing plants and animals influence the market value of farm products. Those processes respond to nutrients, environment, and cultural practices during production. We must identify the basic processes that are responsible for producing desirable and undesirable properties in the products of plant and animal origin. For effective use of the knowledge of basic processes, we must devise means for stimulating the processes that produce desirable properties in farm products and for suppressing those that produce undesirable properties.

For some commodities, we have developed multiple uses. From corn—which is used primarily as feed for livestock—we manufacture a myriad of breakfast foods, oils, sweeteners, starch, alcohol, and many other products. Processing also enhances the utility of other crops, of which potatoes are a notable example. Processes for flame-retardation and wash-and-wear characteristics in cotton and woolen goods are other examples. We must develop new uses for farm products and new methods for enhancing their value.

We must be innovative in research related to animal products. New concepts of nutrition and modification of dietary habits could affect the markets for products of animal origin. Scientists have successfully produced lean hogs, are reducing the sodium content of processed meats, and have experimentally modified the constituents of milk and eggs. With the basic knowledge of the biological processes by which animals metabolize nutrients into meat and other animal products, and with the means for controlling those processes, scientists might be able to improve the nutritional quality and marketability of products of animal origin. Foreign markets, especially industrialized nations such as Japan, offer attractive possibilities for our products from animals. By improving the technology for maintaining—in meat and meat products—the high quality necessary for expanding foreign markets, scientists can contribute to our Nation's economy. Exporting finished products not only improves our balance of payments, but also creates more jobs at home.

Approach 4.2

Develop the Means for Meeting Foreign and Domestic User and Regulatory Requirements Relating to Toxic Factors in Food, Feed, and Other Agricultural Products.

Approach Elements

4.2.1 *Identify and, when necessary, develop the means for removing intrinsic toxic factors of practical significance.*

4.2.2 *Identify and, when necessary, develop the means for removing extrinsic toxic factors of practical significance.*

Safety is important throughout the agricultural system, but it is essential in food. Farm products containing recognized hazards cannot be sold. As a result, producers lose income and the public loses food. Awareness of the importance of safe, highly nutritious foods and safe workplaces is increasing. Throughout production, processing, and distribution, the safety of the food supply is challenged by natural constituents such as enzyme inhibitors, hemagglutinins, goitrogens, and saponins. Processing, cooking, dilution, digestion, and detoxification by metabolism protect us from many natural toxins, but we need information for setting reasonable threshold levels in food and we need to find ways to prevent or control excessive amount.

We could control or eliminate some natural toxins in plant materials that we eat or feed to animals by developing varieties of plants that do not produce toxins. By studying the biochemical processes of cells, we should be able to manipulate the bioregulators of plant metabolism to minimize toxin production. Much of such work will be on crops for livestock feed.

During processing, many compounds—such as salt and sugar—are added to foods. Most traditional food additives are assumed to be safe, but even those can be harmful in excess. Some potentially harmful compounds, such as those produced by browning reactions, can form during processing. Others may result from contamination or may be residues of agrichemicals, antibiotics, or hormones. We must increase our understanding of the toxicology of all potentially harmful compounds and develop methods for detecting and measuring them and their reaction products during processing and storage.

The gastrointestinal illness called "food poisoning" affects as many as 20 million people annually in the United States. Outbreaks continue because (1) producers and consumers are ill informed and do not take known precautions; (2) bacteria, fungi, and viruses that can cause food poisoning are widespread; and (3) we lack basic knowledge about the factors that affect the survival of the organisms and the synthesis of their toxins. To locate and possibly eliminate sources of contamination, we should improve methods for isolating, identifying, and enumerating bacteria, fungi, and viruses that are associated with food. We also should identify—for microbes—the genetic, ecological (physical and chemical), and nutritional factors that interact in foods to favor the development of food poisoning. With that information, we should be able to develop methods that will prevent microbes from growing or forming toxins, or both.

In some years, under some conditions, certain species of fungi invade and produce mycotoxins in such crops as corn, wheat, cotton, peanuts, and tree nuts. Mycotoxins can be ingested with feed and appear in milk and meat. The levels at which mycotoxins become hazardous in food or feed vary among specific toxins produced by different fungi. The Food and Drug Administration of the Department of Health and Human Services has established tolerances for one group of mycotoxins—aflatoxins—in some crops. Using ARS methods, the peanut industry identifies and segregates contaminated peanuts from those that are used directly in foods. For crops that are susceptible to toxin-producing fungi, we must develop sensitive, rapid, and inexpensive methods for sampling and analysis. In assessing the safety of agricultural products, we must identify hazardous etiological agents and evaluate the levels of the hazards to determine whether they have practical importance. For any that are important, we must explore methods for preventing, detoxifying, processing, and grading to eliminate or control the hazard.

Workers who handle farm products can be exposed to conditions that could be hazardous. Byssinosis, for example, is a respiratory ailment that apparently is associated with exposure to cotton dust in the workplace. That association threatens the U.S. cotton industry, and we need scientists in several disciplines to identify the causative factors. Then—by studying all phases of cotton production and processing—they must either try to find cost-effective treatments for cotton or develop handling procedures that would eliminate the problem.

Approach 4.3

Develop Means for Reducing or Eliminating Postharvest Losses Caused by Pests, Spoilage, and Physical and Environmental Damage.

Approach Elements

4.3.1 *Develop improved methods for controlling losses caused by insect pests.*

4.3.2 *Develop improved methods for controlling losses caused by micro-organisms.*

4.3.3 *Develop improved methods for controlling losses caused by internal chemical and biological mechanisms.*

4.3.4 *Develop improved methods for controlling losses caused by physical forces.*

All agricultural commodities are subject to losses during all stages of the marketing system. The extent of total postharvest losses of food worldwide is not known, but for cereal grains, the worldwide loss probably ranges from 10 to 20 percent. The Food and Agricultural Organization estimated that a 10-percent loss would be equivalent to one-half pound of cereal per day for each of 400 million people. The losses of perishable fruits and vegetables are undoubtedly higher. In the United States, about 20 percent of all food produced each year is lost—a loss that amounts to an estimated 137 million tons valued at $5 billion. Estimates of losses caused by pests, alone, range from 3 to more than 10 percent. A 5-percent loss at 1980 retail prices would amount to $14 billion.

Total losses include those of quality and quantity. Both types of loss can occur during all stages—storage, processing, handling, and distribution—of the marketing system. Losses are caused by physical damage, ineffective procedures, and chemical and biological deterioration—but most commonly by the activities of insects and micro-organisms. Often, losses of a given commodity are caused by the interactions among several causes. Some micro-organisms, for example, do not attack sound fruits but do enter wounds inflicted by insects or by rough handling. Thus, the measures devised for controlling losses also interact and cannot be isolated in either theory or practice.

Refrigeration is the critical factor in preserving our perishable agricultural products and in supporting our modern life style. Low temperatures prevent losses that are caused by either pathogens or biological deterioration and also protect against some insects. Scientists have refined procedures for manipulating atmospheres as supplements to refrigeration, but the optimum conditions—of temperature, humidity, and atmosphere—that are regulated for preservation of perishables must be defined for each commodity. We also must explore irradiation as an alternative means of preserving foods for long periods and for use where refrigeration is not available. Foods in sealed containers that are given sterilizing doses of radiation can be stored at room temperature for years without spoiling, and they are not radioactive.

Many of our present methods for controlling insects and other pests that infest commodities during marketing rely upon chemicals whose effectiveness is declining as resistant strains of pests develop and whose safety is being questioned. We must develop a new generation of pesticides that are nontoxic and persistent. Biological controls, and even an insecticide produced by a bacillus, are available for use in the field. Scientists must search natural sources for repellents and pesticides that would be safe for use on commodities during marketing.

To develop new methods for controlling postharvest losses of agricultural products, we need basic knowledge about the biology and ecology of insects and micro-organisms, about the interactions among them, and about their interactions with their hosts and their environments. We must study the basic processes by which the cells and tissues of biological materials deteriorate—even under optimum conditions. Conversely, we need to understand the mechanisms whereby such materials resist deterioration. To devise procedures for minimizing losses from physical damage, we need to understand the biological nature of physical injuries.

Genetic manipulation offers a promising, long-range opportunity for the development of nonchemical methods for controlling losses of agricultural products. We know that some species, and even some strains of species, are more susceptible to attack by pathogens and insects and to physical damage than are others. In cooperation with geneticists, who enhance production by developing resistant strains of plants and animals, scientists in postharvest technology should study commodities, when they are ready for market, for signs of genetic resistance to factors that cause postharvest losses. The introduction—into plants and animals—of genetic material that would either enhance the resistance of their perishable products to attack by insects and pathogens or delay biological deterioration during marketing could be the most effective and least costly means of controlling postharvest losses. Integrated management systems that include all available means for controlling losses hold great promise for increasing the quality and quantity of agricultural products.

Approach 4.4

Develop the Means for Increasing Efficiency of Systems for Processing, Handling, Storing, and Distributing Agricultural Products.

Approach Elements

4.4.1 *Identify system inefficiencies.*

4.4.2 *Devise means for reducing or eliminating inefficiencies.*

4.4.3 *Devise means for efficiently classifying products for exchange in the marketplace.*

4.4.4 *Devise means for meeting domestic and foreign quarantine and other requirements that restrict movement and trade of products.*

A recent assessment of business productivity attributed 67 percent of the growth in both total production and gross product per labor hour to advances in knowledge and technology. Of the approximately 30,000 companies (not counting retail outlets) that process, store, and distribute food, only about 100 have research facilities, and the research of each benefits only the owners and customers of that company. Public research benefits all owners and all customers, but Federal and State support for marketing research declined 19 percent between 1966 and 1970, and the scientific workforce declined 15 percent between 1971 and 1980. During the 1950's, agricultural marketing was second only to agricultural production in terms of industrial productivity, whether measured by output/input indexes or by value added to products. Marketing productivity began to decline in the 1960's and now reflects the escalating costs of labor and all energy-related inputs. Through research, we must find ways to reverse that decline. We must also find ways by which companies that process, store, and distribute agricultural products can reduce costs, still maintain or enhance the quality of those products, and improve their competitive position in foreign markets.

We can start with processing—possibly the most expensive function in the marketing system. Processed foods are the principal items in our diet; more than half our food is processed, and about half our meals are eaten outside the home. The food-processing industry is our fourth largest energy user, and the cost of processing has risen with the

costs of energy and other inputs. To compensate for rising costs, we must both improve the efficiency of present processing methods and develop new, better methods.

In basic engineering studies, we must identify and develop technologies that can reduce or eliminate inefficiencies in processing. For example, we can simulate the processing function in computer models and, by systems analysis, detect the steps with the greatest potential for efficiency improvement. On pilot processing lines, we must determine the effects of each processing step on the nutritional value, yield, and appearance of the final product and then identify the steps in which costly inputs could be reduced. We also should find ways of reducing the escalating cost for disposing of effluents from processing lines. Data from computer models and pilot food-processing lines should be applicable to all early steps in processing that are similar for commercial production of canned, dehydrated, or frozen foods.

We must find new uses for commodities that are underused—or even wasted. Of the 20 billion pounds of agricultural fats and oils produced annually in the United States, 8 billion pounds is unsuitable for food. Despite excesses, we still import certain oils for lubricants, soaps, and detergents and for other specific uses. Inedible fats now are converted to food-grade fatty acids by costly, energy-intensive methods. Enzymatic processing could feasibly enhance the utility of underused agricultural fats and oils. Chemical modification of soybean oil might enable the production of extreme-pressure lubricants—formerly based on sperm oil. We must expand efforts to convert our abundance of agricultural fats and oils into substitutes for petroleum and other imports.

The starch that our crops produce in such abundance has many direct uses. It has been modified chemically into many products, such as "super slurper" for unequaled absorbency and xanthate for removing heavy metals from waste water. Renewable, natural starch polymers can be used in biodegradable plastics, and other derivatives have potential uses in processing rubber and in manufacturing urethane foams. Through basic studies of the chemistry of starch, one of our least expensive agricultural products, we should be able to develop new products with high value and utility.

We could increase the utility or export of many products by finding ways to decrease their cost or to improve their quality and acceptance. Improved methods for tanning hides could help restore the competitive position of the U.S. leather industry and reduce our trade deficit of $2.5 billion for imports of shoes. We should reduce the losses and improve the acceptability of the frozen variety meats that we export (valued at $300 million in 1980). Exports of U.S. citrus fruits are increasing, but we need ways for overcoming foreign restrictions that limit our exports of citrus or other horticultural crops. Scientists must continue to help solve emergency problems—such as the infestation by the Mediterranean fruit fly in California—that affect the marketing of commodities. The most important U.S. exports are grains and oilseeds, and we must develop the new methods needed for inexpensive, rapid sampling and grading so that we can maintain and increase their value and acceptability. The ARS must pursue, with renewed vigor, research that facilitates the profitable marketing of U.S. agricultural products.

Objective 5
Develop the Means for Promoting Optimum Human Health and Well-Being Through Improved Nutrition and Family Resource Management

Nutrition is a key factor in the degree to which we achieve the genetic potentials inherited from our forebears. The potentials include those for growth, reproduction, resistence to disease, longevity, and intellectual development. The great array of foods now available contributes to our unprecedented opportunity to reach those potentials during longer and more productive lives. However, our knowledge of the relationship between our nutrition and the degree to which we achieve our potentials is inadequate. The signs and symptoms of most of the severe nutritional deficiencies are known, but the thresholds of deficiencies that cause mild adverse effects are ill defined. Our inability to specify optimum nutrient intakes for people who are at those ill-defined thresholds of deficiency is a major challenge to research.

Methods for detecting and measuring abnormalities of physiological functions are insensitive and, consequently, the range of function that is considered "normal" has been very wide. New and improved technologies should enable us to refine procedures and techniques for measuring function. Also, our enhanced appreciation that "normal" in the statistical sense does not necessarily mean optimum physiological function for individuals should stimulate our efforts to develop ways for defining "normal" in a physiological sense for each person. We need improved methods for determining whether marginally or mildly deficient diets impair function and for measuring the degree of impairment. Such methods will help us to understand the relationship between nutrient intake and ultimate expressions of our genetic potentials. Future nutrition research, therefore, should be strongly oriented toward defining the effects of mild deficiencies or excesses of nutrients on physiological function and on physical and mental well-being over the whole life span.

57-279 O - 87 - 36

Research on humans must be conducted under carefully controlled conditions so that any sensitive measurements of function that are developed can be applied in a reproducible manner and interpreted properly to discover the relationships between specific nutrients and physiological functions. Those relationships could be studied in groups of people whose suboptimum physiological functions might be related to their nutritional status. Information from such studies could provide the basis for identifying population groups that would benefit the most from programs for nutrition education and intervention. To minimize risk and cost, we routinely study the complexities of nutrition in laboratory animals. However, in the final analysis, findings must be verified in human subjects, and people worldwide could be the ultimate beneficiaries.

Approach 5.1 **Define the Nutrient Requirements of Humans at all Stages of the Life Cycle.**

Approach Elements

5.1.1 *Establish the nutrient requirements of infants, children, and adolescents.*

5.1.2 *Establish the nutrient requirements of pregnant and lactating women.*

5.1.3 *Establish the nutrient requirements of adult humans.*

5.1.4 *Establish the relationship between nutrition and aging.*

Together, the two categories "pregnant or lactating women" and "infants, children, and adolescents" account for about 30 percent of our American population. Common to all individuals in those categories is their need for nutrients to meet the specific demands of growth and development. Nutrients for the fetus, the infant at the breast, the child, and the adolescent must provide for a metabolism that is geared to support the rapid growth of the brain, muscles, bones, and all other tissues and to store energy. Failure to meet those nutritional needs during the periods of rapid growth and development could limit, for a lifetime, both the level of genetic potential reached and the ultimate quality of life. We need research programs that will help us ensure that those nutritional needs are met.

Among middle-aged people, obesity is the most widespread nutritional disorder and may adversely affect the health of 30 percent of the men and 40 percent of the women. People become obese when either their energy intake is too high or their output is too low. With present techniques, however, we cannot determine which factor, or what combination of the two, causes obesity in any given individual. We must discover the dietary factors that affect appetite and explore the consequences of satisfying energy needs with different proportions of the major dietary sources of energy. Through the use of stable-isotope techniques, we must study the metabolism of cabohydrate, fat, and protein in human subjects. The human body contains at least 40 minerals, many of which are essential for function. Only by understanding the biochemical reactions that depend on those minerals as cofactors can we establish optimum intakes. We should define, more specifically, the minimum requirements for known vitamins and determine the effects of megadoses of certain vitamins.

The average American now can expect to live to 73 years of age and, by the year 2000, should expect to live well past 80 years. The significance of nutrition in the aging process can be considered in relation to three observations. First, the efficiency of many physiological functions declines progressively throughout adult life, and nutrition may influence the rate of decline. Second, the etiologies of some chronic diseases and disabilities that are associated with aging are influenced by nutritional factors. Finally, food intake generally diminishes with advancing age, but we have little solid knowledge as a basis for recommending optimum intakes of individual nutrients by older people. We need research programs that address the specific nutritional requirements of the elderly for maintaining their functions.

Approach 5.2

Determine the Nutrient Content of Agricultural Commodities and Processed Foods as Eaten, and Establish the Bioavailability of Their Nutrients.

Approach Elements

5.2.1 *Compile essential data on the nutrient contents of foods as consumed in the United States.*

5.2.2 *Determine bioavailability of nutrients in foods as consumed.*

The establishment of policies and the development of plans for national and international food and nutrition programs require accurate knowledge of nutrient content of food. Since the classic USDA Bulletin No. 28, "The Chemical Composition of American Food Materials," was published in 1896, the Department has published and repeatedly updated a series of food-composition tables. Research organizations, public-health professionals, nutritionists, dietitians, and individuals worldwide rely on the data compiled in USDA Handbook No. 8, "Composition of Foods: Raw, Processed, Prepared." The Human Nutrition Information Service will continue to compile and refine those data. However, to study in certain groups of people the elusive relationship between specific nutrients and physiological function, ARS scientists must chemically analyze the nutrients in the foods that actually are eaten by those people. For such studies, accuracy of the data is critical for trace elements, ultratrace elements, and other nutrients that could be essential in minute amounts, but toxic in larger amounts. Chemical determinations of those nutrients require skilled analysts and are time consuming and costly. To acquire accurate data for the entire diet eaten by individual subjects in the groups studied, we must develop improved methods of sampling and new, automated, and cost-effective methods of analysis.

To understand the role of U.S. agriculture in human health, we should be able to predict the effects that the practices used in all phases of producing, processing, and marketing foods have on the nutritional quality of our diets. The use of fertilizers is an example of practices that can affect the composition of foods. We must study the relationships between the nutrient quality of the samples that are assayed and the history of the foods.

By chemically analyzing samples, we can measure the total amounts of nutrients in a food, but we cannot measure the portion of the total that would be absorbed and used by either laboratory animals or humans. That portion, which indicates the bioavailability of nutrients, can be measured only by bioassays. In our studies of the relationship between diet and the physiological function of people, we must consider the bioavailability, as well as the amounts, of nutrients that foods provide. To determine the bioavailability of specific nutrients in foods, we must develop improved, cost-effective methods for their bioassay. Some nutrients interact with other nutrients, and with some nonnutrients, to alter bioavailability.

Evidence indicates that mineral elements with similar chemical characteristics often compete with one another in plant and animal systems. Zinc and copper interact, and, at marginal levels of nutrient intake, one metal can affect adversely the absorption and metabolism of the other. Interactions of this type are not limited to mineral elements. Absorption of iron is improved by the presence of an animal protein factor or ascorbic acid, or both, and—conversely—absorption of dietary iron, zinc, and calcium can be impaired by phytate and by some components of dietary fiber. People who eat excessive amounts of protein may experience loss of calcium and a weakening of their bones, but some evidence suggests that increased intake of phosphorus prevents calcium losses. We must study specific interactions and assess their importance in human nutrition.

Approach 5.3

Improve the Nutritional Status of Humans and the Well-Being of Families by Making Techniques Available for Assessing the Effectiveness of Nutrition and Home Economics Programs.

Approach Elements

5.3.1 *Provide means for improving understanding of dietary practices, food-consumption patterns, and their determinants through assessments.*

5.3.2 *Develop reliable, efficient, and inexpensive methods for defining nutritional status and evaluating nutrition action programs.*

5.3.3 *Develop methods for improving family economic stability and security.*

We now recognize the need for more sophisticated and accurate methods for assessing the nutritional status of our population. In food-consumption surveys, data usually are collected by the dietary-recall system, which is expensive and prone to errors. The ARS must develop rapid, inexpensive methods for collecting food-consumption data that will accurately reflect dietary habits. In the United States, patterns of dietary practices and habits vary widely among geographic areas, demographic groups, and economic levels. We need more information to understand those patterns and their relation to human health. We must be able to assess and monitor the nutritional status of known high-risk groups—including infants, pregnant and lactating women, the elderly, and the poor. We must also be able to identify other groups of people that could be at high nutritional risk and to monitor changes in their nutritional status.

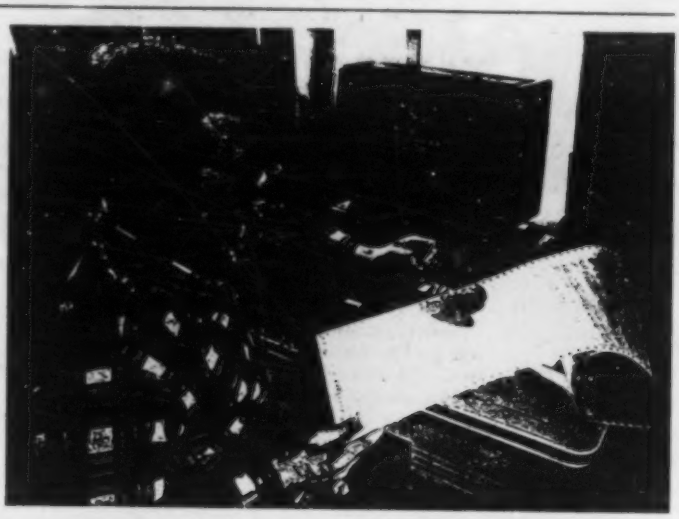
With efficient methods of data collection, scientists should be able to (1) determine what foods people in all groups actually eat and how their eating habits affect their health (2) identify the factors that influence their eating habits; and (3) determine the influence of USDA policies and of programs for nutrition education and intervention on the health, nutritional status, and performance of our citizens.

We know that people with marginal deficiencies in some nutrients suffer altered behavior and impaired performance. Nutrition-related epidemiological research on the many social, environmental, behavioral, economic, cultural, and physiological factors that influence nutritional status will influence the design and evaluation of nutrition action programs. To help ensure the success of such programs, as well as to improve the nutritional status of all our citizens, we must continue our search for biochemical indicators that could be used as simple, specific, and sensitive indexes for evaluating nutritional health. Such indexes also could provide an early warning of potential food and nutrition problems that require remedial action.

As the world's leading producer of food, our agricultural enterprise influences the health of both our citizens and the citizens of the countries that import our farm products. Through its research, ARS will clarify our understanding of the relationship between food and human health and develop improved methods for measuring the true nutritional value of foods for humans. Despite the high cost and complex protocols involved, we must ultimately test our research findings in studies of human subjects. Only the findings from such studies would justify drastic changes of either our procedures for the production, processing, and marketing of foods or our dietary habits. Changes in some of those factors, however, could improve our nutrition and help us increase the degree to which we achieve our genetic potentials.

An integral factor in good nutritional status is effective management of family resources to provide for an adequate amount of nutritious food for all members of the family unit. Some income groups spend the major portion of their wages for food and clothing. However, the food they buy may not meet their nutritional needs. We must find means by which we can help families to manage their resources in a way that will ensure the adequacy of their nutrition and, at the same time, help them achieve economic stability and security.

Objective 6
Develop the Means for Integrating Scientific Knowledge of Agricultural Production, Processing, and Marketing Into Systems That Optimize Resource Management and Facilitate Transfer of Technology to Users



Agriculture must be much more sophisticated in the next century than it is now. We will no longer be able to afford the losses of soil, profligate use of energy and water, and waste of good food that we now tolerate routinely; we must develop systems that conserve those resources. We must integrate data from the basic and applied research—described above in objectives 1 through 5—into models that simulate agricultural activities and practices. Then—by the process of systems analysis—we can compare efficiency among the simulated activities and select those with the most promise for testing and validation in actual experiments. Systems analysis should help increase efficiency in production and marketing, improve assessments of environmental consequences, and foster technology transfer.

Agricultural production must be viewed as a continuum in which financial, human, and natural resources are used for producing, processing, and marketing food and fiber for domestic consumption and export. No part of the continuum can be viewed in isolation because each part affects the other parts. The nutritive value of food and feed and the quality of fiber and other products depend upon the soils, fertilizers, and germplasm used to grow them and the marketing and transportation practices used to handle and deliver them. The costs of agricultural products and the profitability of each phase of agriculture ultimately depend upon the efficiency with which the products are grown and delivered to consumers. As consumers, we are tied fast to farmers and processors, and vice versa. All of us are tied to our resource bases—soil, water, air, germplasm, and energy. Modeling and systems analysis can help us to make this continuum more understandable and manageable and, in many instances, to prevent unwanted side effects.

Many examples, such as improved cropping systems, illustrate the potential power of systems analysis for improving agricultural technology. Traditionally, growers have selected individual technologies "cafeteria style" from those available and tried to use them in their own operations. Modern technologies, however, are becoming so complex and costly that evaluating them by trial and error is no longer practical. To predict which of the available technologies offer the greatest promise of success, we must test them by simulation modeling. For simulations of complex technologies, we must use advanced methods of computing and handling data to incorporate the findings of different scientific disciplines into submodels.

To find the optimum combinations of crops, fertilizers, water management, and pest control for about 10,000 different soils and for the array of diverse climates across the United States, we must integrate the submodels of technologies into models of agricultural systems. To prove which technologies and systems offer the greatest promise for success, we must test the predictions from the models in practical, multivariate field experiments.

Systems analysis also could help to dispel the commonly held notion that high productivity can be attained only at the expense of resource conservation. Because of our great wealth of natural resources, we have not always tried to achieve conservation and productivity simultaneously. The best defense against soil erosion is provided by dense, productive stands of plants that produce ample crop residues. High-yielding crops use about the same amount of water as low-yielding ones, and water-use efficiency is highest when all other growth factors are optimized. The same is true for energy-use efficiency. The challenge, then, is to find ways to reach high and stable levels of crop production with minimum exploitation of limited and expensive resources.

Improvement of the Nation's rangelands offers another opportunity for the use of models. We cannot conduct experiments on all of the more than 30 major rangeland ecosystems in the United States; we can systematically identify needs and make improvements only through the use of models. Models now being developed to quantitatively describe the characteristics of rangelands will simulate the complex functional relationships among soils, water, vegetation, livestock, and climate. Model inputs should include the latest research findings on weed and brush control, water management, reseeding, new grasses, and improved livestock. The natural biota and recreational and scenic values also must be considered. Then, so the results of the simulations will be reliable and useful to ranchers and land managers, we must validate the models by testing their predictions in appropriately located and designed experimental ranges.

We need integrated research in which basic scientific and engineering principles and concepts are applied to the grower-processor-distributor continuum. The location of processing facilities adjacent to production centers and the use of computerized marketing and delivery systems should improve efficiency. Effective coordination among the components of the continuum should prevent excessive losses, maintain the quality of food, and reduce energy consumption.

We need models especially for the development of alternative farming systems. Many people, most of them employed off the farm, use common agricultural practices to farm small acreages. Their operations may be too small for the technologies and marketing systems used by commercial farmers. Many of those people have neither the time to keep up with the latest research findings nor the money to adopt them. Many other people, who may farm either small or large acreages, want to avoid the use of agrichemicals and to maximize the potential for using crop rotations and for recycling animal wastes and crop residues. People in both groups need information that will enable them to make the best long-term use of their resources and to maximize their profits. Many of the same kinds of problems are characteristic of agriculture in the tropical and subtropical zones of the world, and systems analysis can also help solve those problems.

Because modern agriculture is energy-intensive, and energy costs are an increasing burden in all phases of production and marketing, we must conduct research on ways to reduce the dependence of agriculture on fossil fuels. We will include research designed specifically for conserving energy in production, processing, and other phases of agriculture; finding alternative sources of energy, such as biomass, and converting those sources to useful products; substituting wind, solar, and other noncritical sources of energy for fossil fuels; and ameliorating the effects of energy development.

We have sufficient experience with modeling to know that it is effective. The ARS has developed several models—including the Universal Soil Loss Equation (USLE); Modified Universal Soil Loss Equation (MUSLE); Chemicals, Runoff, and Erosion from Agricultural Management Systems (CREAMS); and Simulation of Cotton (SIMCOT)—that simulate major components of agricultural systems. Other organizations have developed economic and management models for agricultural systems that will be useful to ARS. Conversely, agencies such as the Economic Research Service will be able to use those physical and biological models for production forecasts and for economic and policy analyses. The USLE is used worldwide for predicting the effects of management practices on soil erosion. The CREAMS model recently was adopted by the Soil Conservation Service for predicting the effects of different farming practices on water quality.

The ARS and its cooperators have started to integrate submodels into models of large systems. The EPIC (Erosion Productivity Impact Calculator) model, which predicts monthly soil erosion for specific soils by various crop, rotation, and tillage practices, has the following six submodels: (1) soil, water, and nutrient budgets; (2) weather simulation; (3) biomass-crop-growth simulation; (4) tillage- and residue-management simulation; (5) soil erosion; and (6) production-cost budgets. Submodel 6 provides the information—on cost, income, and risk—that farmers need when they adopt conservation practices. The EPIC model should also be useful to many agencies in guiding policy decisions and action programs for crop production and resource conservation; several have expressed interest in using the model. The SPUR (Simulation of Production and Utilization of Rangelands) model is being designed to predict range productivity, evaluate the effects of various management practices, help transfer research results to users, and identify further research needs. It has submodels for climate, hydrology, plants, animals, and insects. Possibilities for technology transfer linkages with economic models and use of remotely sensed data are under investigation for SPUR.

Approach 6.1 **Develop Integrated Systems for Efficiently Producing, Processing, and Marketing Agricultural Products.**

Approach Elements

6.1.1 *Assess and quantify the critical interactions among the different factors needed for producing and marketing food and agricultural products.*

6.1.2 *Develop predictive models for simulating the effects of key physical and biological factors on agricultural productivity and environmental quality.*

6.1.3 *Establish and operate multivariate experiments on integrated agricultural systems to validate models, facilitate technology transfer, and serve as a base for agricultural productivity forecasts.*

6.1.4 *Develop technology for using remotely sensed data to assess and maintain the conditions of our natural resources and to provide information for resource models.*

Problems are typically solved in disciplinary research through the collection of data for individual components—such as soils, plants, insects, and livestock—of a system. Those physical and biological data must be assembled into models of individual systems that can account for the interactions among components. Computer models must accurately and realistically simulate agricultural systems. Their accuracy and validity must be established in appropriate pilot tests and field experiments before the findings can be transferred to users.

The modeling approach has several advantages. First, it is efficient. Time frames of many years can be simulated quickly and inexpensively for many locations and management strategies. Second, an unlimited number of management strategies can be considered, whereas in field experiments only a few can be considered. Third, modeling is a research tool that provides knowledge about agricultural processes and identifies the research that is needed to fill gaps in knowledge. The development of models that simulate specific components of the agricultural system is described in other objectives of the ARS Program Plan. The intent of this objective is to integrate those models of components into models that can simulate even large agricultural systems. Multidisciplinary teams of scientists and engineers will be needed to plan and carry out the modeling and to validate the results.

The ARS has 147 field stations—including instrumented watersheds, range and field research centers, and scientific and engineering laboratories. Cooperating organizations have similar facilities. Many of those stations take measurements and collect data that are useful in the development of submodels and integrated models of systems. "The Census of Agriculture," "Agricultural Statistics," and other references provide information on agricultural production that is useful for developing and testing models. In most instances, multivariate field experiments in various climatic zones or physiographic areas will be required to validate the models. In those experiments, as many as possible of the parameters represented in the models must be individually controlled so that the simulation models will be tested under a wide range of actual conditions. Only then can the results be used with confidence.

An emerging technology—remote sensing—holds great potential for agriculture. Some possible applications include assessing the status of the Nation's resources, estimating the severity of droughts and freezes and their effects on crop yields, scheduling the applications of irrigation water and agricultural chemicals, and forecasting the national or even world production of key agricultural commodities. Many types of sensors may be used, depending upon the kinds of information needed. Types may range from hand-held cameras and radiometers to instruments mounted in airplanes or on satellites. Remote sensing has several potential advantages over conventional technologies, particularly for quickly and inexpensively assessing the condition of crops and soils over large areas.

Data from integrated models, pilot tests, and multivariate field experiments have many practical uses. They can be transferred to potential users, who then can see the actual experimental results and decide which new technologies they want to adopt. Changes in natural-resource bases can be predicted accurately, and steps can be taken to prevent undesirable changes. The field experiments and models will provide a scientific basis for assessing the potential effects, on agriculture, of changes in climate or of increases in carbon dioxide from burning fossil fuels. Similarly, potential adverse side effects of new agricultural technologies can be identified and ways found to mitigate them. Analysis of integrated systems should help to improve the accuracy and timeliness of the Department's forecasts of domestic and foreign production and, in turn, help to reduce speculation and to stabilize commodity markets.

Approach 6.2

Develop Alternative Agricultural Systems, Including Those of Small Scale, That are Less Dependent Upon Nonrenewable Resources and That Are Productive, Efficient, and Sustainable in the Long Term.

Approach Elements

6.2.1 *Develop the means for small-scale commercial farmers and other small-scale producers to maximize efficiency and productivity.*

6.2.2 *Develop productive biological/organic agricultural systems that avoid or minimize the use of nonrenewable inputs, conserve soil and water resources, maintain or increase soil productivity, and produce high-quality products.*

6.2.3 *Develop the knowledge needed for increasing the productivity of tropical/subtropical agricultural systems.*

6.2.4 *Develop systems and technology for reducing the dependence of agriculture on fossil fuels.*

Within the American agricultural community, two groups of producers have some needs that are recognized but are not met through current research programs. Those groups are popularly referred to as "small farmers" and "organic farmers." The inadequacies of those labels notwithstanding, the methods used by the two groups to produce crops and livestock often differ from those used by most large-scale, conventional farmers. Nearly 20 percent of our total food supply comes from the approximately 2 million farms with gross sales of $40,000 or less, and the number of small farms is increasing.

Systems that include the latest technologies for producing, harvesting, processing, storing, and marketing agricultural products could help to reduce costs, ensure conservation of resources, and provide safe and efficient handling of the food produced by that important segment of agriculture. Research on biological nitrogen fixation, biocontrol of weeds and insects, development of better legume varieties, and effects of organic matter on the growth and survival of soil-borne plant pathogens can contribute to systems for organic or low-energy-use farming.

We may be able to develop agricultural production and marketing systems that are applicable to the small-acreage farmer who uses either biological or chemical methods, or a combination of those methods. We should address the needs of the biologically oriented farmer, whether large or small in terms of acreage farmed. The production systems developed should be characterized by less costly methods and by technologies that are safe, sustainable, and environmentally sound. Essential components of the effort should include innovative research to (1) reduce farm production costs while maintaining a high level of sustainable productivity through the development of efficient and diversified crop- and animal-production systems, (2) ensure the conservation of our natural resources, (3) provide safe and economical ways to move agricultural products from the field to the table, and (4) maintain the value and quality of food.

Two other elements of special importance—elements that typically involve a combination of the research efforts described in objectives 1 through 5—are the development of improved farming and marketing systems for tropical and subtropical regions of the world and the development of technologies for reducing the dependence of agriculture on fossil fuels. The ARS must lend its expertise and research capabilities to developing countries, especially those in the tropical and subtropical regions, to help them become self-sufficient. Research in those countries must address the major aspects of agriculture—conservation of resources, improved productivity of crops and livestock, efficient marketing, and improved nutrition of the people.

The ARS also has the capability to help the agricultural industry to conserve fossil energy and, in some instances, to produce alternative energy sources or petrochemical substitutes. Agriculture has the potential for using wind, solar, and other energy sources for activities such as pumping irrigation water, drying grain, and heating farm buildings. Those potentials must be assessed both for conserving energy and for reducing production costs. The waste from one process or activity may be the fuel or feedstock needed for another process or activity, and systems analysis will help identify such opportunities. Biomass, unlike fossil fuels, is renewable, and many scientists think that recent advances in biotechnology hold promise for the use of biomass as a feedstock for industrial processes that yield such products as rubber, resins, terpenes, proteins, waxes, lignin, a variety of carbohydrates, and many others. The production of crops for biomass, chemical feedstocks, and other industrial uses potentially could help farmers to diversify their operations. Through such diversification of U.S. agriculture, farmers would have alternative markets, and the Nation would have domestic supplies of strategic materials for industry.

Implementation Strategy—Policies

Strategic planning is a continuous process of making decisions that are based on the best information available, organizing people and resources to carry out those decisions, and evaluating results against expectations. The Program Strategy describes the kinds of research identified by ARS scientists as necessary to meet the short- and long-term needs of agriculture and presents the minimum number of research approaches needed to meet the goal and objectives of the ARS Program Plan. The research approaches are based on current scientific knowledge and will change as knowledge advances or as the research needs of agriculture change.

The purpose of the Implementation Strategy is to provide guidelines for implementing those portions of the Program Strategy that ARS selects as most likely to succeed in achieving the objectives. As shown in figure 4, the ARS Implementation Strategy includes policies, a Six-Year Implementation Plan, and resource allocations. This section contains the statements of ARS policies for the following key activities:

- National planning and coordination,
- Determination of program content,
- Establishment of priorities,
- Program implementation and management,
- Review and evaluation, and
- International activities.

These policies will guide the development of the ARS Six-Year Implementation Plan and the resource projections now being prepared, as well as the development of operational plans for specific programs. The USDA agencies develop budgets on a 3-year cycle; the Implementation Strategy will encompass two budget cycles. The Administrator of ARS will manage the Agency in accordance with the Six-Year Implementation Plan to mobilize the physical, financial, and human resources of ARS that are necessary for addressing the high-priority needs of agriculture and its beneficiaries.

The policies are statements that establish the principles and standards by which organizational objectives will be realized. Policies must be developed for an organization's key functions, responsibilities, and activities. They also must be understood and followed by all members of the organization so that the efforts to achieve the organization's goals will be cohesive. Policies guide decisions and form a basis for collaboration and teamwork in planning and decisionmaking. The following policies provide a stable framework for maintaining the continuity and flexibility needed to foster scientific excellence and high productivity in the ARS research effort.

Policy 1
National Planning and Coordination

The Administrator Will Operate ARS as a Managed Activity Coordinated by Plan

The Program Strategy describes the research needed to respond to the formidable challenges facing U.S. agriculture. The ARS, the principal intramural research agency in USDA, is—in turn—challenged to focus its scientific resources on the timely solution of the problems it addresses. The ARS Administrator will ensure that needed plans are developed, updated periodically, and implemented to deploy the physical and human resources of ARS to that end. Such plans will provide a framework and sound foundation for:

- Assigning responsibilities for program and administration within the agency;
- Coordinating research across ARS programs, regions, and areas to ensure effective teamwork and to minimize duplication;
- Coordinating ARS research programs with progress of other research performers, such as the State Agricultural Experiment Stations and industry, to ensure that efforts are efficient and complementary;
- Meeting the research needs of those who use agricultural research, including other Federal agencies;
- Setting priorities for allocating and redirecting resources and developing budget requests to promote scientific excellence and to use the talents of the Agency most efficiently;
- Ensuring that effort is productive and balanced among the 6 objectives and 24 research approaches of the ARS Program Plan, as defined in this document;
- Ensuring that problems are addressed by the most appropriate means in terms of key scientific disciplines, teamwork, and technical approach;
- Ensuring that physical and financial resources are available and used effectively;
- Reviewing and evaluating progress toward the achievement of the objectives; and
- Enhancing the opportunity for ARS scientists to innovatively apply their expertise to critical regional, national, and international problems.

The Six-Year Implementation Plan will be the key document in the overall ARS Program Plan. The development and maintenance of the Six-Year Plan are responsibilities of the Deputy Administrator of ARS and the National Program Staff (NPS). Working with line managers, the NPS—in accordance with that Plan—will assess the full spectrum of scientific needs of the Agency, assess the resources that are available for reassignment, and identify program areas that lack resources. Based on the results of

that work, the NPS will develop options and provide, to the Deputy Administrator, recommendations for resource allocations. The Administrator will then select the research programs for implementation by line managers. He will also select from the options those for which the NPS and the ARS Budget Division will develop budget proposals for submission to the Department. Each year, the NPS will adjust the Six-Year Plan based on budgetary decisions and national priorities. Line managers are responsible for updating their operational plans, in accordance with those decisions and priorities, and for implementing their plans. The ARS scientists are responsible for keeping staff members and line managers abreast of the latest scientific advances and opportunities for progress and for ensuring the scientific excellence of their programs. A coordinated ARS effort will ensure that public resources are expended on scientifically excellent and innovative efforts directed toward high-priority problems.

Policy 2
Determination of Program Content

The ARS Research Program Will Include the Full Range of Activities Needed To Achieve the Six Objectives of the Program Strategy

For steady progress toward achieving the six objectives of the Program Strategy, ARS will balance its efforts between basic and applied research. Basic research produces fundamental knowledge that is an essential scientific resource. In their applied research, ARS scientists will draw on that resource to meet the immediate needs of USDA action agencies, other Federal agencies, and users of ARS research findings. By maintaining the balance between basic and applied research, ARS will competently address the critical problems presented in the 6 objectives and 24 research approaches. Basic research programs will be targeted on problem areas in which inadequate fundamental knowledge limits progress. Other programs will exploit existing knowledge bases and breakthrough areas that have a high probability of significant practical payoff. The ARS programs will emphasize long-term, high-risk research that other organizations probably would not attempt. Interdisciplinary research teams will be formed, reorganized, and redirected as needed to ensure that effort is efficiently focused and that the research leads that promise the widest spectrum of benefits are pursued.

The ARS will concentrate on problems of regional, national, and international scope and importance. Problems of more limited scope, such as adapting research findings to local needs and practices, are generally addressed by the State Agricultural Experiment Stations or other research performers unless particular ARS expertise is needed. The ARS will not conduct research that can be conducted better or on a more timely basis by industry. Cooperative research by ARS and State and industrial scientists will be encouraged as an efficient means for increasing the overall benefits that accrue from public investments in agricultural research.

Policy 3
Establishment of Priorities

The Deputy Administrator is Responsible for Establishing Priorities in the Six-Year Implementation Plan and the Derived Budgets. The Administrator Ensures That the Priorities Are Consistent With the Goals of the Department

The priorities established formed the basis for determining program content, for operational planning, and for resource allocations in ARS in three major ways. Priorities will be the foundation for updating the Six-Year Implementation Plan and for planning annual allocations and budget requests. Priorities will guide the allocation of resources in the regions and areas and among competing operational needs. An evaluation of progress in and the plans of each research unit will form the basis for allocations. Research leaders and individual scientists will consider the Agency's priorities in determining which lines of research to pursue within the overall mission of their laboratories and in conformance with the Six-Year Implementation Plan.

Priority setting is complex and dynamic. It is an interactive process among staff and line scientists and includes considerations of both the scientific community and research users. Decisions by the Secretary of Agriculture, Office of Management and Budget, and the Congress will determine the ARS appropriation and can affect the allocation of funds to specific locations and areas of research. Within ARS, individual scientists, along with area and center directors and regional administrators and their staffs, will significantly influence priorities based on their analyses of needs for equipment, facilities, and personnel for exploiting scientific opportunities. Outside of ARS, the Joint Council on Food and Agricultural Sciences and its regional subcommittees, the Users Advisory Board, leaders of farm organizations, industrial groups, and professional societies will influence priorities. The USDA action and regulatory agencies that depend upon ARS for research—agencies such as the Animal and Plant Health Inspection Service, Soil Conservation Service, Food and Nutrition Service, Food Safety and Inspection Service, Agricultural Marketing Service, and Foreign Agricultural Service—will also influence priorities. At times, the research needs of agencies such as the Environmental Protection Agency, Agency for International Development, Department of Defense, National Aeronautics and Space Administration, Extension Service, Forest Service, and Bureau of Land Management will enter the process. Analyses and projections by the Economic Research Service and other agencies also will be considered.

For the setting of priorities, the Administrator will rely on the Deputy Administrator and the NPS to plan, articulate, and evaluate national ARS programs. The NPS identifies research opportunities, research that is conducted by other organizations, and research needs that are expressed by user and advisory groups. The NPS develops recommendations for program redirections and budget requests. Those recommendations will be included in action memoranda, option papers, budget analyses, summaries of program reviews and evaluations, or other appropriate documents. As the direct recipient of the information described above, the Deputy Administrator will establish and articulate ARS priorities. The NPS will update the Six-Year Implementation Plan and, with the ARS Budget Division, develop budgets for that Plan.

The main criteria for setting priorities and allocating resources will be:

- Consistency with the objectives and goals of the Congress, the Department, and the Agency;

- Need for the research as expressed by ARS scientists, user groups, Federal agencies, and the general scientific community;

- Potential benefits expected from achieving the stated objectives;

- Research capabilities and capacity of the scientists, laboratory, or program;

- Probability of success;

- Cost of conducting the research; and

- Amount and kind of research effort conducted by other research organizations.

Several factors may constrain the allocation of resources and kinds of research that ARS conducts and limit the flexibility in resource use. The following factors, which include major constraints, must be considered:

- Availability of scientific expertise. Successful research depends upon the training and experience of individual scientists and upon the teamwork that evolves within and among laboratories. For both individuals and groups, many years are required to reach peak productivity. To help ensure the availability of scientific expertise, the ARS Office of Higher Education will provide guidance on postgraduate and other training opportunities for ARS scientists and others.

- Limitations of geography, climate, and soil. For valid results, certain types of research, especially field research, must be conducted at problem sites and over extended periods.

- Nature of the problem. Much ARS research requires costly facilities and equipment that are problem-specific. Quarantine facilities and special equipment for work on recombinant DNA and foreign animal diseases are examples.

- Sequential nature of research. Often, one phase of research must be completed before the next phase can be started.

- Continuous adaptation of biological systems. Examples are the resistance of crop pests to chemical controls and the genetic improvement of crops that may introduce new vulnerabilities. Goals and priorities must be revised to meet new problems as they arise.

No totally objective formula is possible for setting priorities and allocating resources for research. Priority setting for research is the exercise of informed judgment. It is based on the criteria and constraints listed above; all the factors are important at some level of decision making. At the project level, scientific criteria and experience will predominate. At the national level, scientific criteria must be balanced with Federal policies and with the needs of action agencies and other users of research. It is the task of the Administrator, Deputy Administrator, and the NPS to achieve such a balance so that ARS may provide its scientists with the long-term stability and the firm commitments that are needed for creative research.

Policy 4
Program Implementation and Management

The Regional Administrators are Responsible for the Development and Implementation of Operational Plans for Achieving the Objectives of ARS. The Administrator Is Responsible for Overall Coordination and Execution of the Program

The ARS operates by means of coordinated line and staff activities and responsibilities. Regional Administrators are responsible for field operations managed by four regional offices and staffs, by area directors, and by directors of major research centers. The Deputy Administrator of ARS, located at Headquarters, is responsible for the management and operation of the NPS. The ARS management cadre is responsible for research programs carried out at approximately 150 worldwide locations by 7,600 full-time and 1,000 part-time ARS employees.

The NPS is responsible for developing and providing overall leadership for national research programs in accord with policies 1 and 3. The regional administrators are responsible for operations and operational planning within their respective regions. The staffs for regional program planning and review, the area and center directors, and scientists prepare operational plans in consultation with and subject to review by the NPS. The regional administrators, working with the area and center directors, are responsible for the direct supervision and management of approved research programs and projects. Management support services provide for personnel and for procurement, fiscal, and other functions. Regional administrators are responsible for allocating the resources needed to implement ARS program elements within their regions. They manage the Research Grade Evaluation and Merit Pay Systems by which individual scientists and support personnel are evaluated and rewarded, including the recognition of interdisciplinary research and teamwork.

Line managers play a key role in coordinating research in ARS with that in the Agricultural Experiment Stations, Cooperative Extension Service, Soil Conservation Service, and other agricultural groups of State and regional scope. Through close working relationships with the directors of State Agricultural Experiment Stations, joint research projects, cooperative agreements, and extramural projects are developed as needed to ensure efficient use of ARS personnel and resources.

Line and staff personnel will work together to maintain the integrity and scientific excellence of national programs while efficiently and effectively using ARS resources. The NPS will consult with the regions in developing the ARS priorities and the Six-Year Implementation Plan; the regions will consult and review with the NPS to ensure that the operational plans are consistent with the research objectives and with the priorities of the Six-Year Plan.

Policy 5
Review and Evaluation

The Deputy Administrator Is Responsible for the Systematic Evaluation of Programs and of Progress Toward Achievement of the Six-Year Implementation Plan

The review and evaluation of research programs at many levels in the Agency serve to identify areas of significant progress, major constraints to further progress, emerging research problems and opportunities, and research that can be discontinued. That information will be used in setting priorities, planning and implementing redirections, developing budgets, and revising the Six-Year Implementation Plan and the operational plans.

The NPS is responsible for reviewing national programs and for evaluating their progress and consistency with the Six-Year Plan. To successfully carry out that responsibility, members of the NPS will be recognized experts in their fields and will be expected to maintain their knowledge of the latest scientific aspects of their assigned areas of responsibility. The NPS members will also need broad experience and understanding of interdisciplinary research to recognize and exploit opportunities in related fields or to function as coordinators of problem-solving interdisciplinary teams. They will be prepared to provide authoritative advice as required. Thus, the NPS members serve the Agency as guardians of the continuing relevance and correctness of the technical directions of the ARS program.

The NPS, the Regional Program Planning and Review Staff, and the area and center directors will have operational responsibility for reviewing and evaluating specific programs and units. To spare staff resources, program evaluators will consider the largest practical aggregation of research units. In addition to the appropriate staff and line managers, review and evaluation teams can include top ARS scientists or national technical advisers; representatives from cooperating State Agricultural Experiment Stations, action agencies, and farm and industrial organizations, or other knowledgeable people who can contribute. The review and evaluation teams will develop a formal list of findings and recommendations for implementation by line managers, the scientists, or members of the NPS. (See Directive 600.6.) The regional administrators will then document, and forward to the Deputy Administrator, the plans for and the actions taken to implement the recommendations of the review and evaluation teams.

Area and center directors will review, annually, each research unit and laboratory under their supervision to assess progress on the operational plans and to ensure conformance with the Six-Year Implementation Plan. Although technical matters may be considered, the main purpose of those reviews will be to evaluate operational capability and performance. The adequacy of available physical, financial, and human resources should be assessed, based on the technical objectives to be achieved. Special attention will be given

to identifying opportunities for enhancing technical and leadership capabilities. Findings from and recommendations that result from those reviews will be formally communicated to the Deputy Administrator and to the Regional Program Planning and Review Staff offices.

Scientific and technical excellence demands a continuing review and evaluation of progress by the scientists performing the work. Scientific decisions at the experimental level are best made by those scientists.

Appropriate management information systems will be developed and maintained to meet the specific needs of the Administrator and of the deputy and regional administrators.

Policy 6
International Activities

The ARS Conducts Research and Participates in Technology Exchange in Foreign Countries To Complement and Strengthen Domestic Research Programs, To Support International Trade and Development, and To Carry Out Activities Authorized by the Agriculture and Food Act of 1981

The Administrator of ARS has operating responsibility for international activities. The Assistant to the Administrator for International Activities is responsible for allocation of human and financial resources to foreign activities. The Deputy Administrator and the NPS are responsible for planning, setting priorities, and evaluating international research activities that are an extension of the domestic programs described in the Six-Year Implementation Plan.

As specified in the Agriculture and Food Act of 1981 (Public Law 97-98), ARS also will support U.S. and foreign initiatives that directly benefit U.S. agriculture and provide a substantial contribution to world agriculture. The ARS will work directly with other USDA agencies, such as the Foreign Agricultural Service, Office of International Cooperation and Development, and Animal and Plant Health Inspection Service; other Government agencies, such as the Agency for International Development, Departments of Defense and Commerce, National Science Foundation, and State universities; and international institutions, such as the Food and Agriculture Organization, World Bank, International Atomic Energy Agency, and World Health Organization to produce the greatest benefits from research and technical-exchange programs.

Appendix

The Planning Process

The Agricultural Research Service Program Plan has several purposes. It presents the goal and long-term objectives of the Agency. Those objectives address the current and future needs of agriculture for managing its natural resources, producing and marketing food and other products, and providing nutritious and wholesome foods at reasonable costs. The Plan describes the kinds of research that scientists of the Agricultural Research Service (ARS) think will be needed to achieve the objectives. The intent is to communicate, in an understandable way, the relevance and importance of the agricultural sciences for the future well-being of the United States. The Plan describes the way in which ARS plans to mobilize its scientific resources to help achieve the objectives with a balanced strategy of basic and applied research. The Plan also provides for the continuous review, evaluation, and updating of ARS research to ensure both scientific excellence and continued relevance.

In the first step in the planning process, the goal and six objectives were established. Then, members of the National Program Staff (NPS) drafted a set of 67 proposed courses of action, or research approaches, for achieving the objectives. Each approach was assigned to a selected ARS scientist for further development. Those 67 scientists, who represented many of the 150 ARS locations, then—in turn—enlisted the help of many other scientists to ensure full consideration of commodities, disciplines, and problem areas. More than 500 scientists contributed to the effort. During a period of about 3 months, the scientists developed written materials that defined the scope and scientific content of the approaches. A coordinator for each objective assisted in organizing the written materials. Because of the high cost of holding meetings and workshops, most participants used an electronic mail system to permit maximum interaction and to speed communications.

The scientists concentrated on science and research strategies and avoided defending or projecting current operating programs and organizational structures. Those issues would be addressed later in plans for operations and programs. Scientists organized each research approach into one or more approach elements, which—in turn—contained one or more project areas. A project area was defined as a significant block of scientific work (3 to 10 scientists working with support for 1 year) needed to implement the approaches. The scientists provided the following information for each approach element and project area:

- The nature of the problem to be solved and its scientific and agricultural importance;
- State-of-the-art or current research status and critical research needs or events for further progress;
- The kinds of results expected (reports, vaccines, germplasm, models, etc.) and length of time needed to produce those results;
- Potential benefits and impacts that can be expected if the research is successful;

- Probability of successful achievement; and
- Relative priority of the research.

That information was used to help develop and define the final set of research approaches, approach elements, and project areas. Duplication was eliminated, and only the approaches that were essential to achieve the objectives were selected. Objective coordinators and members of the NPS then developed brief narrative summaries for the final research approaches and approach elements.

The final 24 research approaches that were selected from the 67 originally proposed describe research areas that offer important opportunities for increasing the productivity of agriculture. Examples of those opportunities are improving germplasm resources, reducing losses of crops and livestock, increasing the effectiveness of the marketing sector, and conserving soil and water resources. The research areas described are of lasting importance to agriculture, other agencies, and the public and have high potential for continued progress. A catalog of project areas has been prepared for use in resource projections, but it will not be published. Members of the NPS are now developing the resource projections needed for use in the Six-Year Implementation Plan, which, in turn, will guide the preparation of operational plans by line managers. The Six-Year Implementation Plan and the operational plans will be revised, as appropriate, to reflect the latest scientific findings and most urgent needs of agriculture.

Acknowledgments

This publication was developed under the supervision of Thomas J. Army, Deputy Administrator, NPS, ARS, and chairman of the planning committee, with the guidance of Terry B. Kinney, Jr., Administrator, ARS, USDA. Many others—including vice-chairman Timothy Blosser and objective coordinators Landy Altman, Reginald Handwerk, Charles Kiddy, Waldemar Klassen, Stephen Rawlins, Richard Ridgeway, and Donald Therriault, who made up the planning committee—were deeply involved. Special acknowledgments go to the planning committee and to all of the ARS scientists who participated in development of the Program Strategy. The ARS national research program leaders, NPS chiefs, and others on the NPS played key roles in coordinating and organizing materials for this publication. Warren C. Shaw and Paul A. Putnam were cochairmen of a task force for development of policies, and Essex E. Finney, Jr., was chairman of a committee that assessed future needs for agricultural products and resources.

The Economic Research Service, USDA, provided useful background information and projections. Geri Richmond and Ted Tschudy of the Organization and Management Development Staff were extremely helpful in providing an orderly approach to the planning procedure. The secretarial staff of the NPS was most helpful at all times. Albert R. Grable and Gerald G. Still prepared the final document, and E. Jean Loyd and Annelle C. Black edited it. Michelle Moran and Margaret Theurer typed the many drafts and final copy.

We are indebted to Louis M. Carrese, Associate Director for Program Planning and Analysis, National Cancer Institue, National Institutes of Health, Public Health Service, U.S. Department of Health and Human Services, Bethesda, Md., who was most helpful and generous with his time in presenting seminars, providing advice, and answering questions raised by the planning committee.

The photographs illustrating the goal and objective 2 are by Grant Heilman Photography, Lititz, Pa. The objective 5 cover photograph is by Thomas Zimmerman, Freelance Photographers Guild, New York, N.Y., and the objective 5 text photograph is by Richard Steedman, Stock Market Photography, New York, N.Y.

APPENDIX:	ARS OBJECTIVES, APPROACHES, AND APPROACH ELEMENTS	25

Introduction

In the Program Strategy of the Agricultural Research Service (ARS) Program Plan (U.S. Dept. Agr. Misc. Publ. 1429, issued 1983), ARS scientists identified the broad array of research necessary to meet the short- and long-term needs of agriculture. The research was organized into the 6 Objectives, 24 Approaches, and 98 Approach Elements (see Appendix) needed to meet the stated goal. In this 6-Year Implementation Plan, ARS presents those portions of the research described in the Program Plan that will be pursued in the planning period FY 1984-FY 1990.

The Program Plan was developed with a long-term view (20 to 50 years) and under the assumption that funds would be unlimited. In contrast, the 6-Year Implementation Plan was developed under the assumption of finite resources. The 6-Year Plan also reflects the perception, by ARS, of the short-term goals of the Administration and the Congress.

As a statement of ARS program priorities and overall research direction for the planning period, this publication will guide ARS scientists who develop research projects, along with other Agency decision makers at all organizational levels. It also will provide important information to organizations that cooperate with ARS, use ARS research findings, or provide resources for ARS activities. Plans cannot be static. The ARS must respond to expected and unexpected technological advances and research opportunities and to changes in public policy. Therefore, the 6-year plan will be reviewed and updated annually.

The section on Research Strategies, which follows, describes the broad research strategies that will influence the content and direction of the ARS program for the 6-year planning period.

The Summary on Program Emphasis and Deemphasis outlines those portions of the program, by and within objectives, that ARS intends to implement in the 6-year planning period. It specifies the program areas targeted to receive increased or decreased emphasis and projects allocations of funds to the year 1990.

The section on ARS Operational Plans describes the translation of the 6-year plan into operational plans and activities.

Research Strategies

In the Program Plan, the following three major problems were identified as challenges to the long-term ability of the United States to sustain agricultural productivity:

- o World food needs, which will certainly increase with world population over the next 40 years, will be partially met by the United States as a major supplier of agricultural commodities;
- o The decline in quantity and quality of land and water resources continues as more marginal land is put into use and as nonrenewable ground water is exhausted;
- o The annual rate of increase in agricultural productivity is showing signs of declining, and acceleration depends heavily on new technological breakthroughs.

For the period FY 1984 through FY 1990, these long-term challenges must be considered in conjunction with more immediate problems of high-production costs and loss of markets that are faced by U.S. agriculture. Not all these problems can be solved through research; some are problems associated with international trade and monetary policy. However, to the extent these problems might be solved through research, ARS, as the national agricultural research agency, must address them and perform that essential research not being accomplished by others.

Key strategies that guided development of the 6-year plan are as follows.

STRATEGY 1 THE ARS WILL MAINTAIN EMPHASIS ON MISSION-ORIENTED FUNDAMENTAL, LONG-RANGE, HIGH-RISK RESEARCH

For several decades, the generation of fundamental agricultural knowledge, the "seed corn" of technology, has not kept pace with its exploitation into useful technology. That knowledge has been used to solve relatively tractable problems at the expense of generating the new knowledge needed to solve resistant problems. Helping to fill the knowledge gap is clearly a Federal research responsibility, particularly in those rapidly advancing areas that offer potential for increasing agricultural productivity. In the judgment of ARS managers, mission-oriented, fundamental research should account for about 50 percent of the ARS program between 1984 and 1990. Historical and current data for the ARS investment in fundamental research and analysis of the changes in program emphasis projected for the 6 years indicate that the investment in fundamental research will not vary from 50 percent by more than plus or minus 10 percent.

STRATEGY 2

THE ARS WILL INCREASE EMPHASIS ON INTEGRATIVE SYSTEMS RESEARCH

In solving broad regional and national agricultural problems, ARS must consider the effects of a wide spectrum of interactive variables and constraints. To significantly increase agricultural productivity, ARS must devise ways to measure and test factors that affect the efficiency of complex management systems. The intensive farming practices required to increase future productivity require increasingly expensive inputs that will significantly increase the financial risks if crops fail. When agricultural productivity is pushed to the limits, rules of thumb and traditional criteria are inadequate bases for decisions. New management systems and models that account for interactions among components of complex agricultural systems and that accurately predict the consequences of alternative decisions are needed. The ARS is well-qualified for leading team efforts to integrate research approaches that can produce solutions to national problems. For example, producers and processors need predictive management models for making the decisions necessary for timely, appropriate responses to variations in market, weather, pests, costs, and other constraints.

STRATEGY 3

THE ARS WILL EMPHASIZE RESEARCH APPROACHES DIRECTED TOWARD INCREASING EFFICIENCY OF OPERATION AND QUALITY OF PRODUCTS, REDUCING THE USE OF NONRENEWABLE RESOURCES (SOIL, WATER, FUELS) AND INCREASING THE DOLLAR VALUE OF AGRICULTURAL PRODUCTS

Over the long term, U.S. farmers must increase their margin of profit. To that end, ARS will pursue the approaches that are directed toward efficient production, processing, and marketing of high-quality products. Efficiency should help reduce costs of all operations, increase the difference between farmers' dollars of input and of return, and improve the competetive position of U.S. products in domestic and foreign markets. The high quality of farm products should provide similar benefits. With highly efficient operations throughout the agricultural system and reasonable profits for all segments of the system, marginal lands might be withdrawn from production and nonrenewable resources conserved. Such actions should maintain the flexibility the United States might need to respond to national emergencies or shortfalls in production.

Summary of Program Emphasis and Deemphasis

Since 1966, Federal funds for agricultural research have remained about the same on a constant-dollar basis. Recognizing the probability that ARS will continue to have constant-dollar budgets in the foreseeable future, the 6-year plan identifies research program areas targeted for increased emphasis and decreased emphasis within the 1982 level of funding. Resource allocations must be shifted, over time, to achieve a program balance that will be consistent with ARS objectives.

Figure 1 gives the percentage distribution of FY 1982 ARS program funding ($413 million), by the six objectives in the Program Plan. This distribution represents the base from which shifts are planned.

Figure 1. Distribution of funds among objectives of the ARS Program in 1982.

Before decisions were made on the reallocation of funds among objectives of the ARS program, the following factors were considered:

- Production by U.S. agriculture exceeds current domestic needs.
- The United States is facing an indefinite period of surpluses of major agricultural commodities.
- U.S. agricultural products are losing competitiveness in world markets.
- New products are needed for American farm commodities to more successfully compete in world markets.
- Lower production costs are needed for American farm products.
- The U.S. natural resource base is declining.
- Increased emphasis is needed on basic science in agriculture to replenish the dwindling store of basic knowledge.
- More ARS emphasis is needed on fundamental and applied research to increase efficiency of production.
- Integrative systems research is needed to improve the efficiency of U.S. agriculture.
- Improved human nutrition is a national priority.

On the basis of these factors, ARS will appreciably increase its emphasis on commodity conversion and delivery and human nutrition research and modestly increase its emphasis on soil and water conservation and integrative systems research. Without increased funding, ARS must carefully reallocate funds to support essential increases at the expense of some areas of research on plant and animal production. Fundamental productivity research continues to be a national priority. However, significant portions of the conventional, applied, and developmental research components of the ARS program must be assumed by other sectors of the full agricultural research system that are capable of sharing the responsibilities for carrying out that research. Within the ARS productivity research programs that will be continued, long-term fundamental studies will be emphasized to generate the basic knowledge and technology for solving major problems in the efficiency of plant and animal production. Figure 2 gives the planned percentage distribution of total ARS funding, by objectives, for the year 1990.

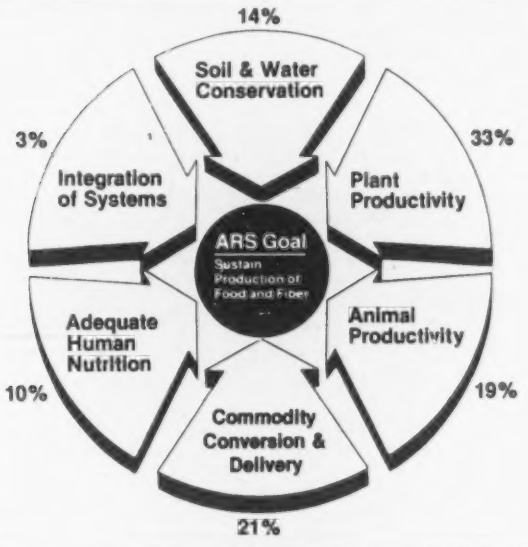

Figure 2. Planned distribution of funds among objectives of the ARS Program for the year 1990.

Table 1 gives the 1982 and targeted distributions of ARS funds, by both dollars and percentages. Also given are the shifts of funds planned within and across objectives to achieve the new program balance.

Table 1 indicates that a total of $75 million in the current base of the ARS program--$33 million across objectives and $42 million within objectives--is targeted for reallocation.

Details of the reallocations for achieving targeted program balance among the approaches and approach elements within each of the six objectives appear in tables 2-7 and in respective bar graphs, figures 3-8. In the tables, only the net shifts of funds from or into an approach element are indicated. Anticipated redirections of funds within approach elements are not indicated. In the figures the differences between the length of the open bar (present level) and the solid bar (targeted level) for each approach element represent the planned amount and direction net change. Major program areas for emphasis and deemphasis are listed after the tables and bar graphs.

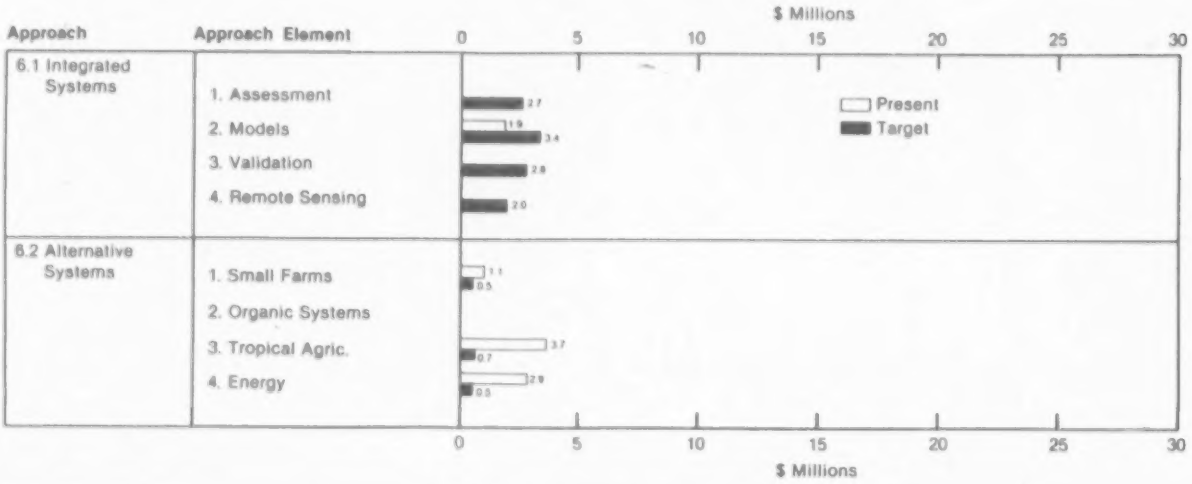

FIGURE 8.--Objective 6. Integration of Systems: Present and targeted approach element allocations.

SPECIFIC PROGRAM CHANGES

Program areas targeted for emphasis and deemphasis within each objective are listed in the outline below. The programs listed are those of major focus and do not include all changes at the approach and approach element levels.

1. Soil and Water

   A. Emphasis: Basic technology for resource assessment, base data for land/water systems analysis and predictive modeling, and programs to improve management of water resources to minimize plant stress.

   B. Deemphasis: Land shaping, engineering-structure development, field evaluation of structures, groundwater recharge, irrigation-hardware development, water-harvesting programs, and municipal and waste utilization.

2. Plant Productivity

   A. Emphasis: Acquisition and maintainence of the genetic diversity of plants, beneficial organisms, and pest species; basic studies on genetic engineering and biology of plants, beneficial organisms and pests; fundamental aspects of crop growth, yield barriers, and management methods.

   B. Deemphasis: Varietal breeding, selected small-commodity programs, location-specific cultural and management practices, pollination and honey production, applied engineering development of equipment for crop production and protection, control of pests with limited geographic or economic significance, applied research on technology for agricultural chemicals, and programs with little potential economic impact.

3. Animal Productivity

   A. Emphasis: Basic studies, at biochemical and physiological levels, on controlling genetic variation; basic research on improving genetic resistance of animals to diseases and parasites; basic studies on increasing reproductive efficiency; mechanisms of nutrient absorption and synthesis of protein and fat; genetic manipulation of pathogens for controlling and preventing disease; and integration of efficiency elements of animal production into total management systems.

B. Deemphasis: Development and field testing of killed and attenuated vaccines, applied insect-control systems, waste management, applied selection and mating programs, and nutrient-limitation work.

4. Commodity Conversion and Delivery

A. Emphasis: Basic mechanisms controlling quality characteristics of marketed products and of means for their genetic and internal control; basic studies on mycotoxin prevention and elimination; basic studies on microbial spoilage agents and pathogen-host associations for preventing contamination; new utilization approaches for exploiting biotechnological advances, adding dollar value, and expanding markets; basic studies of host-pest interactions for reducing losses; basic mechanisms of biodeterioration in harvested plant and post-slaughter animal materials; export grading; and insect and microbial barriers to export.

B. Deemphasis: Food composition, regulatory approvals and registrations, applied product and process improvement, inherent toxic-factor identification and screening, physical losses, and identification of systems inefficiencies.

5. Adequate Human Nutrition

A. Emphasis: Determination of bioavailability of food nutrients and of nutrient requirements for infants, children, and adolescents; nutrition/aging relationships; data bases for improving evaluations of nutritional status.

B. Deemphasis: Nutrient requirement of adults and pregnant/lactating women, nutrient content of foods, dietary practices, and food-composition patterns.

6. Integration of Systems

A. Emphasis: Assimilation and integration of biological and physical research data into systems for analyzing complex interactions of two or more research areas; for example, animals, plants, and environment. Provision of bases for problem identification, and development and validation of predictive models.

B. Deemphasis: Rural housing, small-scale farming, organic farming, tropical agricultural systems, and energy.

ALTERNATIVE FUNDING STRATEGIES

If funding increases, ARS will continue to redirect funds within objectives and approaches as outlined in this 6-year implementation plan and will further increase and accelerate efforts in the high-priority program areas identified for increased emphasis. The 1990 targeted program balance (percentage distribution of funds among objectives) will be maintained with the increases.

If funding decreases, ARS will reduce programs identified for decreases in tables 1-7, while maintaining as near as possible current allocations of funding in areas of program emphasis.

ARS Operational Plans

The ARS 6-year implementation plan provides targets and directions for change in broad program areas. Programs will be adjusted incrementally through internal management and annual budget processes. In some cases, the increment of change in a given program area may be large and abrupt, either early or late in the 6-year planning period; in other cases, the changes will be gradual or in stepwise reallocations throughout the period. In yet others, the planned changes may be modified before actual achievement because the 6-year implementation plan will be updated annually as appropriate to national priorities and policies at the time and depending, partly, on the extent of program changes in the respective current or previous years.

ARS will concentrate effort in high priority program areas and develop centers of specialized research activity. ARS will pursue research for which it can provide the critical mass of resources needed to achieve the planned objectives.

On the basis of this 6-year implementation plan, ARS managers and scientists will develop operational plans that specify (1) project areas for emphasis and deemphasis; (2) timetables for action; and (3) deployment of human, physical, and capital resources for ensuring efficient progress toward the objectives of the ARS Program Plan.

Appendix: ARS Objectives, Approaches, and Approach Elements

OBJECTIVE 1	DEVELOP THE MEANS FOR MANAGING AND CONSERVING THE NATION'S SOIL AND WATER RESOURCES FOR A STABLE AND PRODUCTIVE AGRICULTURE
Approach 1.1	Develop the Technology for Assessing and Predicting Long-Term Changes in the Quantity and Quality of Soil, Water, and Air Resources Available to Agriculture.
Approach Elements	
1.1.1	Develop improved techniques and systems for assessing, predicting, and monitoring changes in the productive capacity of land and soil resources.
1.1.2	Develop improved techniques for assessing and predicting water supplies and their quality.
1.1.3	Develop improved techniques for assessing and predicting the effects of weather and air quality on agricultural productivity.
Approach 1.2	Provide the Technology Needed for Improving, Protecting, and Restoring the Productive Capacity of Agricultural Soils.
Approach Elements	
1.2.1	Develop cost-effective conservation technologies for controlling soil loss from croplands and rangelands.
1.2.2	Devise methods for maintaining and improving soil fertility and the chemical and biological properties of soils for optimum crop production.
1.2.3	Devise techniques for improving, maintaining, or restoring the physical conditions of soils that are needed for optimum crop production.
1.2.4	Devise methods for safely and efficiently recycling municipal and agricultural wastes through croplands.
Approach 1.3	Develop Improved Water-Management Systems and Practices To Achieve Effective and Efficient Use of Water Resources.
Approach Elements	
1.3.1	Optimize the use of water by plants in irrigated and nonirrigated croplands and rangelands to improve and stabilize productivity.
1.3.2	Develop methods for increasing, conserving, and managing water supplies available for agriculture, for improving water quality, and for reducing cropland damage from flooding.

1.3.3	Improve technology for storing and distributing water supplies efficiently and for improving irrigation, drainage, and salinity-control systems and practices.
Approach 1.4	Develop Subsystems and Models That Integrate the Use of Soil, Water, and Air Resources for Optimum Management of Major Land Resource Areas.
Approach Elements	
1.4.1	Develop systems and models for designing resource management strategies that optimize agricultural production and resource conservation.
1.4.2	Develop systems and models for designing resource management strategies that will satisfy the needs of nonagricultural resource uses.
1.4.3	Develop systems and models for designing resource management strategies that are compatible with environmental quality goals.
OBJECTIVE 2	DEVELOP THE MEANS FOR MAINTAINING AND INCREASING THE PRODUCTIVITY AND QUALITY OF CROP PLANTS.
Approach 2.1	Broaden the Germplasm Resources of Plants and Beneficial Organisms To Ensure Maximum Genetic Diversity for Improved Productivity.
Approach Elements	
2.1.1	Develop an understanding of the taxonomic relationships among plants, beneficial organisms, and pests as the basis for research to enhance crop production and protection.
2.1.2	Collect, evaluate, preserve, and make accessible new sources of germplasm of plants and other organisms and assess their potential for meeting agricultural and industrial needs.
2.1.3	Collect, evaluate, preserve, and distribute germplasm of plants and beneficial organisms and of strains of pests that are valuable in pest-management programs.
Approach 2.2	Select and Modify Germplasm of Plants, Beneficial Organisms, and Pests.
Approach Elements	
2.2.1	Devise new methods for modifying germplasm of plants, beneficial organisms, and pests.

	2.2.2	Improve genetic populations of range, pasture, forage, and turf.
	2.2.3	Improve genetic populations of field crops.
	2.2.4	Improve genetic populations of horticultural and specialty crops.
	2.2.5	Improve genetic populations of beneficial organisms, and develop inferior strains of pests that will be useful in pest-management programs.
Approach 2.3		Develop Improved Production Practices for Maintaining and Increasing Crop Productivity and Quality and for Reducing Costs.
Approach Elements		
	2.3.1	Develop knowledge of basic plant growth and development processes of crop species and of micro-organisms of agricultural importance.
	2.3.2	Develop basic ecological principles and improved cultural and management practices for range, pasture, and forage.
	2.3.3	Develop basic ecological principles and improved cultural and management practices for field crops.
	2.3.4	Develop basic ecological principles and improved cultural and management practices for horticultural and specialty crops.
	2.3.5	Develop basic principles for and improved methods of pollination and honey production.
	2.3.6	Discover principles for and develop criteria and specifications for improving the efficiency of agricultural production and protection equipment and practices.
Approach 2.4		Discover Principles and Develop Improved Methods for Reducing Crop Losses Caused by Weeds, Diseases, Insects, Nematodes, and Other Pests.
Approach Elements		
	2.4.1	Develop knowledge of growth, development, and behavioral and population processes of insects as a basis for discovering control principles.

2.4.2 Develop knowledge of etiology, epidemiology, and pathogenicity of plant pathogens as a basis for discovering control principles.

2.4.3 Develop knowledge of growth, development, and behavioral processes of nematodes as a basis for providing control technology.

2.4.4 Provide technology for protecting range, pasture, forage, and turf from losses caused by insects, nematodes, pathogens, and other pests.

2.4.5 Develop principles for protecting field and horticultural crops from losses caused by insects, nematodes, and pathogens.

2.4.6 Develop knowledge of the basic biology of weeds for determining their vulnerability to control.

2.4.7 Develop control technology for reducing losses caused by weeds in forage crops, pastures, rangelands, turf, aquatic environments, and noncroplands.

2.4.8 Develop control technology for reducing losses caused by weeds in field and horticultural crops.

2.4.9 Develop fundamental principles of biological control for pests of crop plants.

2.4.10 Discover principles and develop agricultural chemical technology for reducing crop losses and for modifying plant growth for improved crop protection and production.

2.4.11 Develop fundamental principles for the control of vertebrate pests.

Approach 2.5 Develop Improved Methods for Integrating the Crop- and Pest-Management Practices Needed for Higher and More Stable Levels of Crop Production.

Approach Elements

2.5.1 Develop the means for assessing crop conditions, and identify the factors that limit yields of major crop commodities.

2.5.2 Develop growth and management models for optimum production of crop commodities.

OBJECTIVE 3	DEVELOP THE MEANS FOR INCREASING THE PRODUCTIVITY OF ANIMALS AND THE QUALITY OF ANIMAL PRODUCTS.
Approach 3.1	Increase the Genetic Capacity of Animals for Production.
Approach Elements	
3.1.1	Devise optimum selection and mating procedures for obtaining high levels of animal performance and improved product quality.
3.1.2	Devise procedures for selectively manipulating genetic material to improve desired characteristics.
3.1.3	Determine genetic variation in biochemical, physiological, and behavioral traits of animals, and devise ways for using the information to accelerate genetic improvement.
3.1.4	Improve genetic resistance of animals to diseases and internal and external parasites.
Approach 3.2	Improve the Efficiency of Reproduction and Reproduction-Related Biological Processes.
Approach Elements	
3.2.1	Increase the number of offspring reared per male and female maintained.
3.2.2	Increase efficiency of germ cell and embryo production, transfer, and storage and of techniques for producing more offspring of superior quality.
3.2.3	Increase efficiency and persistence of lactation and egg production.
Approach 3.3	Improve Animal Nutrition and Feed Efficiency To Increase Productivity and Product Quality.
Approach Elements	
3.3.1	Remove nutrient limitations to production.
3.3.2	Reduce losses and inefficiencies in nutrient use, and explore alternative sources of nutrients.
3.3.3	Devise nutritional and physiological means for modifying the rate of synthesis and the composition of animal products.

Approach 3.4	Develop Ways To Prevent or Control Losses From Diseases, Parasites, and Toxicants and Other Substances That Limit Animal Performance and Reduce the Quality of Animal Products.
Approach Elements	
3.4.1	Improve methods for diagnosing and identifying agents that cause losses, and improve methods for assessing those losses.
3.4.2	Establish the roles of environmental stresses and nutrition in losses from diseases and parasites.
3.4.3	Characterize the mechanisms by which animals become infected and are affected by diseases and parasites.
3.4.4	Devise new and improved methods for preventing or reducing death morbidity, and other losses from diseases and parasites.
3.4.5	Prevent, control, or eliminate losses from natural or synthetic substances to which animals may be exposed.
Approach 3.5	Develop Means for Controlling Insects, Ticks, and Mites That Affect Animals and Man.
Approach Elements	
3.5.1	Improve methods of detecting infestations and assessing losses.
3.5.2	Examine mechanisms by which insects, ticks, and mites cause harmful effects.
3.5.3	Devise new and improved methods for reducing losses from insects, ticks, and mites that affect animals and man.
3.5.4	Integrate control technologies into systems approaches for managing insects, ticks, and mites that affect animals and man.
3.5.5	Develop means for protecting humans from insects and insect-borne diseases.
Approach 3.6	Devise Means for Improving and Integrating Procedures and Facilities for Production and Transport of Animals To Increase Productivity, Reduce Costs, and Minimize Stresses.

Approach Elements

3.6.1	Assess environmental impacts and shelter needs for farm animals.
3.6.2	Develop facilities and equipment for feedstuff storage, processing, and distribution.
3.6.3	Develop facilities and equipment for improving animal performance and labor efficiency in production systems.
3.6.4	Develop improved facilities and equipment for handling and transporting animals.
3.6.5	Develop systems for managing and using manure efficiently as a resource.
3.6.6	Devise integrated management practices for maximizing animal productivity and product quality, while minimizing stress.
3.6.7	Evaluate, for optimum use of resources, management programs that integrate all productivity elements under various environmental conditions.

OBJECTIVE 4 — DEVELOP THE MEANS FOR ACHIEVING MAXIMUM USE OF AGRICULTURAL PRODUCTS FOR DOMESTIC MARKETS AND EXPORT.

Approach 4.1 — Develop Means for Enhancing the Inherent Properties and Uses of Agricultural Materials.

Approach Elements

4.1.1	Characterize the basic, physical, chemical, and aesthetic properties of plant and animal materials that enhance their usefulness.
4.1.2	Identify the biological and biochemical mechanisms, in plants and animals, that affect properties of agricultural materials.
4.1.3	Devise means for regulating and controlling the biological processes that enhance usefulness.
4.1.4	Devise concepts for innovative and improved processes and products.

Approach 4.2	Develop the Means for Meeting Foreign and Domestic User and Regulatory Requirements Relating to Toxic Factors in Food, Feed, and Other Agricultural Products.
Approach Elements	
4.2.1	Identify and, when necessary, develop the means for removing intrinsic toxic factors of practical significance.
4.2.2	Identify and, when necessary, develop the means for removing extrinsic toxic factors of practical significance.
Approach 4.3	Develop Means for Reducing or Eliminating Postharvest Losses Caused by Pests, Spoilage, and Physical and Environmental Damage.
Approach Elements	
4.3.1	Develop improved methods for controlling losses caused by insect pests.
4.3.2	Develop improved methods for controlling losses caused by micro-organisms.
4.3.3	Develop improved methods for controlling losses caused by internal chemical and biological mechanisms.
4.3.4	Develop improved methods for controlling losses caused by physical forces.
Approach 4.4	Develop the Means for Increasing Efficiency of Systems for Processing, Handling, Storing, and Distributing Agricultural Products.
Approach Elements	
4.4.1	Identify system inefficiencies.
4.4.2	Devise means for reducing or eliminating inefficiencies.
4.4.3	Devise means for efficiently classifying products for exchange in the marketplace.
4.4.4	Devise means for meeting domestic and foreign quarantine and other requirements that restrict movement and trade of products.

OBJECTIVE 5	DEVELOP THE MEANS FOR PROMOTING OPTIMUM HUMAN HEALTH AND WELL-BEING THROUGH IMPROVED NUTRITION AND FAMILY RESOURCE MANAGEMENT.
Approach 5.1	Define the Nutrient Requirements of Humans at all Stages of the Life Cycle.
Approach Elements	
5.1.1	Establish the nutrient requirements of infants, children, and adolescents.
5.1.2	Establish the nutrient requirements of pregnant and lactating women.
5.1.3	Establish the nutrient requirements of adult humans.
5.1.4	Establish the relationship between nutrition and aging.
Approach 5.2	Determine the Nutrient Content of Agricultural Commodities and Processed Foods as Eaten, and Establish the Bioavailability of Their Nutrients.
Approach Elements	
5.2.1	Compile essential data on the nutrient contents of foods as consumed in the United States.
5.2.2	Determine bioavailability of nutrients in foods as consumed.
Approach 5.3	Improve the Nutritional Status of Humans and the Well-Being of Families by Making Techniques Available for Assessing the Effectiveness of Nutrition and Home Economics Programs.
Approach Elements	
5.3.1	Provide means for improving understanding of dietary practices, food-consumption patterns, and their determinants through assessments.
5.3.2	Develop reliable, efficient, and inexpensive methods for defining nutritional status and evaluating nutrition action programs.
5.3.3	Develop methods for improving family economic stability and security.

OBJECTIVE 6	DEVELOP THE MEANS FOR INTEGRATING SCIENTIFIC KNOWLEDGE OF AGRICULTURAL PRODUCTION, PROCESSING, AND MARKETING INTO SYSTEMS THAT OPTIMIZE RESOURCE MANAGEMENT AND FACILITATE TRANSFER OF TECHNOLOGY TO USERS.
Approach 6.1	Develop Integrated Systems for Efficiently Producing, Processing, and Marketing Agricultural Products.
Approach Elements	
6.1.1	Assess and quantify the critical interactions among the different factors needed for producing and marketing food and agricultural products.
6.1.2	Develop predictive models for simulating the effects of key physical and biological factors on agricultural productivity and environmental quality.
6.1.3	Establish and operate multivariate experiments on integrated agricultural systems to validate models, facilitate technology transfer, and serve as a base for agricultural productivity forecasts.
6.1.4	Develop technology for using remotely sensed data to assess and maintain the conditions of our natural resources and to provide information for resource models.
Approach 6.2	Develop Alternative Agricultural Systems, Including Those of Small Scale, That are Less Dependent Upon Nonrenewable Resources and That Are Productive, Efficient, and Sustainable in the Long Term.
Approach Elements	
6.2.1	Develop the means for small-scale commercial farmers and other small-scale producers to maximize efficiency and productivity.
6.2.2	Develop productive biological/organic agricultural systems that avoid or minimize the use of nonrenewable inputs, conserve soil and water resources, maintain or increase soil productivity, and produce high-quality products.
6.2.3	Develop the knowledge needed for increasing the productivity of tropical/subtropical agricultural systems.
6.2.4	Develop systems and technology for reducing the dependence of agriculture on fossil fuels.

APPENDIX 4

Report of the DoD Laboratory Management Task Force

July 1980

OFFICE OF THE UNDER SECRETARY OF DEFENSE

WASHINGTON, D.C. 20301

RESEARCH AND ENGINEERING

19 AUG 1980

MEMORANDUM FOR THE DISTRIBUTION

SUBJECT: Forwarding of the DoD Laboratory Management Task Force Report

The Report of the DoD Laboratory Management Task Force is forwarded for your information and use. This Report, which has been approved by the Under Secretary of Defense for Research and Engineering, provides the basis for the Laboratory Management Task Force to proceed, in conjunction with responsible offices in OSD and the Military Departments, to develop action plans to implement the recommendations presented.

I wish to thank the many individuals who contributed to the work of the DoD Laboratory Management Task Force and who participated in developing the Service Laboratory Resource Management plans. The working processes of the Task Force provide an excellent example of how effective communications and teamwork can deal with complex management problems.

These are but the initial steps in our program to maintain the vitality of our DoD Laboratories and to increase their productivity. I solicit the continued support of all members of the DoD R&D management community in this worthwhile endeavor.

Arden L. Bement, Jr.
Deputy Under Secretary of Defense
for Research and Engineering
(Research and Advanced Technology)

Attachment

DoD LABORATORY MANAGEMENT TASK FORCE

FIRST INTERIM REPORT TO THE SECRETARY OF DEFENSE

CHAIRMAN DR. ARDEN L. BEMENT, JR.
DEPUTY UNDER SECRETARY OF DEFENSE
FOR RESEARCH AND ENGINEERING
(RESEARCH AND ADVANCED TECHNOLOGY)

JULY 1980

This presentation will provide orientation to the work of the Laboratory Management Task Force and an overview of progress to date. The report contains recommendations for action at various levels of the Office of the Secretary of Defense (OSD) and within the Military Departments. We are firmly convinced that implementation of these recommendations can significantly enhance the vitality of the laboratories and improve the productivity of DoD Research, Development, and Acquisition (RDA) activities.

If implementation is initiated promptly, we believe that the benefits should be fully apparent within two to three years. We also believe that with sustained management attention the contribution of the laboratories can be brought to an all-time peak within the 1980's.

Upon acceptance of the report, it will be provided to the Secretariats of the OSD and the Military Departments, to the Service Acquisition Chiefs, to the Joint Logistics Commanders, and to others including the laboratory communities.

REPORT OUTLINE

BACKGROUND	2
TASK FORCE PARTICIPATION	3
PREVIOUS STUDIES	4-7
THE CURRENT SETTING	8-10
LABORATORIES PROFILE AND ROLES	11-12
TASK FORCE FINDINGS	13
RECOMMENDED ACTIONS	14
ACTION SUMMARIES	15-42
SERVICE PLAN SYNOPSES	43-53

The presentation will cover the above general outline. We will indicate how this effort got started, who the principal players have been, and what those before us did; then give our feelings for the current situation. We will then summarize our findings and recommendations for action, and provide a set of specific analyses and steps for progress.

We emphasize that the Report overview is supported by an extensive array of documentation and participant examinations, including individual Service Laboratory Resource Management Plans.

BACKGROUND

- FIRST JOINT MEETING OF DoD LABORATORY DIRECTORS–JUNE 1978
- REPORT OF AD HOC GROUP TO EXAMINE IMPACT OF MANAGEMENT CONSTRAINTS ON THE DoD LABORATORIES– SEP 1979
- SECDEF MEMORANDUM ESTABLISHING DoD LABORATORY MANAGEMENT TASK FORCE (LMTF)– OCT 1979

The perception that a multiplicity of resource controls on laboratory operations were counterproductive became increasingly evident in the late 1970's. At the 1978 Laboratory Directors Conference, the laboratory community expressed its growing alarm about the adverse effects that individual controls collectively produce. This concern was reiterated at the Congressional level, particularly by the House Armed Services Committee during Fiscal Year 1979 hearings. The declining adequacy of the U.S. military equipment was clearly the concern underlying this attention.

As a result, an ad hoc task group of senior level executives examined the apparent situation. They concluded that the laboratories were being seriously injured by a collection of controls and that the situation was common to the three Services.

Accordingly, these findings were brought to the attention of the Secretary of Defense and he directed the establishment of a formal DoD Laboratory Management Task Force (LMTF) to address ways to improve the vitality of our laboratories. The Task Force operates under the chairmanship of the Deputy Under Secretary of Defense for Research and Engineering (Research and Advanced Technology) and is composed of a broad array of senior level representatives from within the DoD.

TASK FORCE PARTICIPATION

COMPOSITION	PRIMARY SUPPORT
OSD	
OUSDRE (R&AT)	OASD (MRA&L)
OASD (MRA&L)	OUSDRE (R&AT)
OASD (C)	
DARPA	
ARMY	
OASA (RDA)	OASA (RDA)
ODCSRDA	HQ DARCOM
HQ DARCOM	HDL
	ARDL / ATL
NAVY	
ASN (RE&S) / DNL	OPNAV
NADC	NADC
NRL	DTNSRDC
	NSWC
	NOSC
	ONR
AIR FORCE	
OASAF (RD&L)	AFWAL
AFSC-DL	AFSC
AFSC-DLZ	

The Task Force initiated operation in January 1980, and is aggressively pursuing the issues as directed by the Secretary of Defense. Service representation is at three levels: the Secretariat, the Staff, and the Field. Additionally, numerous organizations have been assisting the principal members.

REPRESENTATIVE MAJOR STUDIES OF DoD LABORATORIES

- SECDEF TASK 97 STUDY GROUP (1961)
- BELL REPORT (1962)
- TASK 97 ACTION GROUP (1962-1964)
- FEDERAL COUNCIL FOR SCIENCE & TECHNOLOGY (1961-1973)
- CIVIL SERVICE COMMISSION (1967-1968)
- TASK GROUP ON DEFENSE IN-HOUSE LABORATORIES (1971)
- ARMY & NAVY MATERIEL ACQUISITION REVIEWS (1973-1978)
- DoD LABORATORY UTILIZATION STUDY (1975)
- GAO REPORTS ON FEDERAL R&D LABORATORIES (1979)

We are aware that laboratories—whether in Government or industry—are a lightning rod for concerns about science and engineering. The DoD laboratories are no exception. They have been the subject of intensive and recurring studies for several decades. We have tracked studies as far back as one by Dr. Von Karman in 1945.

The slide shows a few of the more significant studies of the past 20 years. We believe it worthwhile to take a few moments to highlight some of the general findings, recommendations, and results of such studies.

PRINCIPAL FINDINGS OF PAST STUDIES

- LABORATORIES VITAL TO DEFENSE RDA
- LABORATORIES CONTRIBUTION IS CONSTRAINED BY–
  - INHIBITING PROCEDURES
  - INADEQUATE PAY
  - AGING FACILITIES
  - MISMATCHED WORKLOAD AND MANPOWER
- CORRECTIVE ACTIONS ARE REQUIRED

Rather consistently, past studies have produced findings essentially the same as those summarized on the chart. Considering the fact that these study groups frequently were composed of eminent people from outside and within the DoD, this general consistency is especially notable. Even within the detailed findings we have found the same high degree of focus.

57-279 O - 87 - 38

GENERAL RECOMMENDATION OF PAST STUDIES

- IMPROVE FACILITIES AND STAFF
- UPLIFT QUALITY OF TECHNICAL LEADERSHIP AND MANAGEMENT
- GIVE LABORATORY LEADERSHIP AUTHORITY AND FLEXIBILITY

Equally noteworthy has been the consistency of the various recommendations.

OBSERVATIONS

- POSITIVE ACTIONS TAKEN WHICH IMPROVED THE ENVIRONMENT FOR LABORATORIES CONTRIBUTION
- BUT–ITS TIME FOR REVITALIZATION
  - CONSTRAINTS ON RESOURCES
    - MULTIPLE
    - INCREASING
    - LEAD TO INEFFICIENCY
  - SHORTAGE OF QUALIFIED SCIENTISTS AND ENGINEERS
    - HIGHLY COMPETITIVE MARKET
    - COMPLEX PERSONNEL AND MANPOWER POLICIES
  - MANAGEMENT AUTHORITY WEAKENED

In general, the recommendations of these past studies have not been ignored. To varying degrees corrective actions have been undertaken—occasionally with striking success. For example, the Bell report resulted in the provision of specific discretionary funds for laboratory directors. The Civil Service Commission study produced significant improvements in personnel procedures. On the other hand, Project REFLEX, a highly regarded initiative to improve civilian manpower management, lost its momentum when the Services were placed under increasingly austere manpower constraints.

R&D managers are fully familiar with encumbrances such as those shown—and with their potential for undermining the contribution of laboratories. The Secretary of Defense recently stated that "periodic reattack of the problem is needed to scrape off the barnacles... fundamental change should also be looked at but will be harder to get barring some catastrophic twist." We agree fully, and, like our predecessors, are working to provide a positive perspective.

THE URGENCY

THE CENTER OF GRAVITY IN THE COMPETITION BETWEEN THE TWO WORLD OPPOSED SYSTEMS IS NOW TO BE FOUND PRECISELY IN THE FIELD OF SCIENCE AND TECHNOLOGY, ... MAKING FURTHER INTENSIVE DEVELOPMENT OF THE LATEST SCIENTIFIC-TECHNICAL ACHIEVEMENTS NOT ONLY THE CENTRAL ECONOMIC BUT ALSO A CRITICAL POLITICAL TASK, AND GIVING QUESTIONS OF SCIENTIFIC-TECHNICAL PROGRESS ... DECISIVE SIGNIFICANCE.

L. I. BREZHNEV

What then is new? What justifies renewed efforts to ensure the vitality of the DoD laboratories? The situation has been brought into all too sharp a focus by Mr. Brezhnev. The U.S. is faced with an extraordinary challenge in the area of technology. The technology challenge is not predominantly economic as in the competition with Germany, Japan, and several others. Technology has now become an extremely critical element in the protection of our national liberty.

THE RDA IMPERATIVE
• IMPROVE MANAGEMENT OF OUR SCIENTIFIC AND TECHNOLOGICAL RESOURCES
• EXPAND OUR TECHNOLOGICAL OPTIONS
– STRENGTHEN TECHNOLOGY
– MAKE BETTER USE OF INDUSTRY BASE
– INCREASE COOPERATION WITH OUR ALLIES
• FIELD SYSTEMS WHICH EFFECTIVELY MEET MISSION NEEDS

Inherent in the urgency must be a continuing concern over the growing quantitative disparity between deployed U.S. and Soviet weapons. Equally important must be concern over significant advances in the quality of Soviet technology and field weapons. These concerns formulate the RDA imperative.

Through the years the in-house laboratories have had key involvements across the spectrum from research to stockpile. As major participants in the technology base and systems acquisition process, the cruciality of their performance becomes increasingly important in times of national urgency. They are a principal player for transferring DoD work to universities and industry. They have major responsibilities both in leading and in assessing the defense RDA work of the private sector.

LABORATORIES PROFILE

- 73 LABS SERVICE MANAGED
- 60,000 PEOPLE–80% CIVILIAN–MEDICAL & AIR FORCE LABS–50% MILITARY
- $5.2 BILLION ANNUAL PROGRAM–40% IN-HOUSE, RDTE $3 BILLION–50% IN-HOUSE
- PHYSICAL INVESTMENT $4 BILLION 50/50 REAL PROPERTY/EQUIPMENT
- SMALL AND LARGE <100 TO >4000
- PHYSICAL SCIENCE, LIFE SCIENCE, & PERSONNEL
- RESEARCH THROUGH THE FULL RDA SPECTRUM

There are over 70 formally recognized DoD in-house laboratories—some large, some small—performing work in the physical, life, and social sciences in support of military and military civil works programs of the DoD. They constitute a large investment of dollars and manpower. Nearly two-thirds of the annual cash flow is RDTE money. About one-half of the R&D funds are contracted to universities and industry; the other half is retained by the laboratories to carry out roles requiring in-house personnel—including extensive activities necessary to support contract work. The balance of these funds are predominately procurement monies that are used for first acquisition of materiel systems and associated support, particularly product improvements. Most of this money is used for industry contracts.

DoD LABORATORY ROLES

- IDENTIFY, EVALUATE, EXPLOIT TECHNOLOGY HANDS-ON
- MINIMIZE TECHNOLOGICAL SURPRISE
- SOPHISTICATED BUYER
- PROCESS TECHNOLOGICAL CONCEPTS TO PROGRAM REALITY
- PERFORM OR MANAGE PROGRAM EXECUTION
- SYSTEMS SUPPORT
- UNDERTAKE ACTIVITIES HAVING EXTRAORDINARY RISK OR REQUIRING QUICK REACTION
- PROVIDE CORPORATE TECHNICAL MEMORY

As major participants in the technology base and in the systems development and acquisition process, the laboratories must respond to DoD needs to:

— Achieve equipment improvements which reduce the impact of projected manpower constraints;

— Obtain lower equipment production, operation, and support costs; and

— Direct substantial R&D effort toward the longer term technological deficiencies and opportunities—particularly through the revitalization of our technology base, the stimulation of prototyping and the use of mature U.S. and Allied technology, and the reduction of intelligence asymmetry and "technological surprises" in the face of a determined and well-supported Soviet competition.

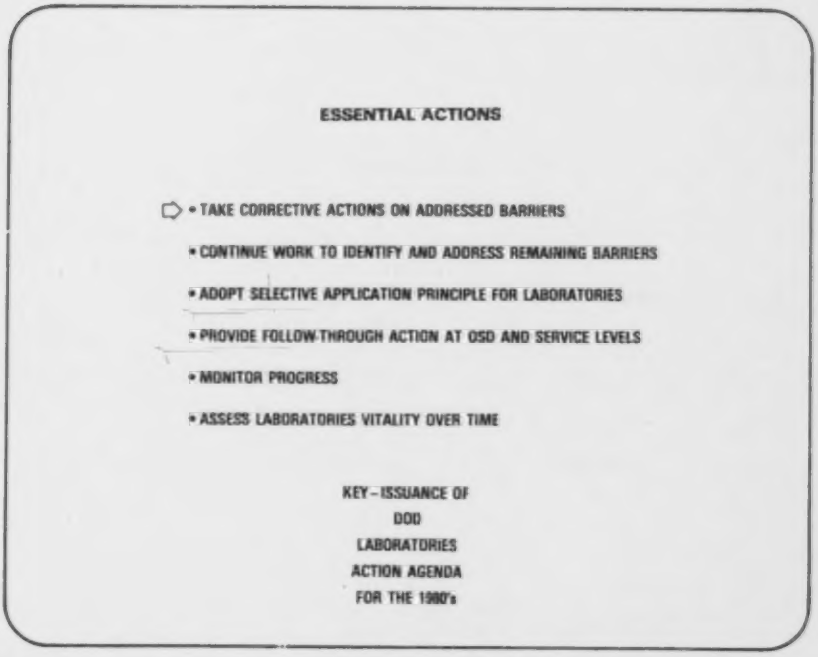
LMTF FINDINGS

THERE ARE SIGNIFICANT BARRIERS IMPEDING EFFECTIVE ROLE PERFORMANCE:

- **MANAGEMENT FLEXIBILITY**
- **STAFF**
- **FACILITIES**
- **EQUIPMENT**

The Task Force's initial job was to access institutional problems. The members compiled analyses of management controls negatively impacting their respective areas of responsibility. This analysis centered primarily on personnel, funding, and contracting issues. Extensive background material was developed. A significant number of barriers have been identified. Most of these are restrictions and limitations placed on the use of specific categories of resources by functional offices outside the RDA management chain. They are usually imposed independently of one another and are often suboptimized with respect to the overall responsibilities of the DoD laboratories. The Task Force then set about determining whether these negative controls were common to all Service laboratories or, conversely, whether the Services were applying controls in notably different manners. The Task Force formulated tentative recommendations which, if implemented, have a high probability of improving the operating environment of the laboratory community.

As suggested by the Secretary of Defense, the Task Force also worked to identify actions of a more fundamental nature which would achieve a high degree of flexibility within a framework of controls that are operationally feasible and acceptable to the OSD and the Services. A significant challenge to the Task Force was their goal of balancing relief mechanisms with monitorship techniques in which top management can have high confidence.



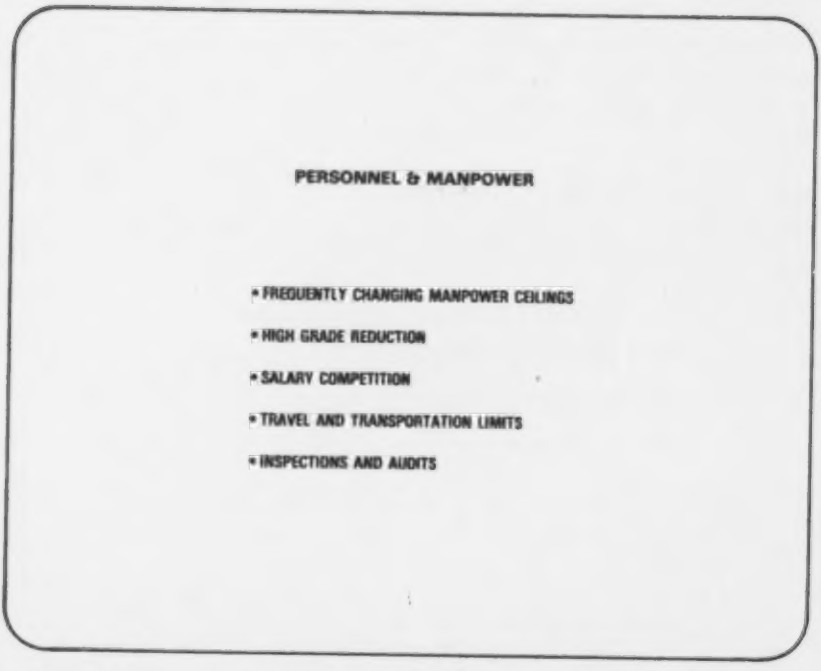
ESSENTIAL ACTIONS
• TAKE CORRECTIVE ACTIONS ON ADDRESSED BARRIERS
• CONTINUE WORK TO IDENTIFY AND ADDRESS REMAINING BARRIERS
• ADOPT SELECTIVE APPLICATION PRINCIPLE FOR LABORATORIES
• PROVIDE FOLLOW-THROUGH ACTION AT OSD AND SERVICE LEVELS
• MONITOR PROGRESS
• ASSESS LABORATORIES VITALITY OVER TIME
KEY–ISSUANCE OF
DOD
LABORATORIES
ACTION AGENDA
FOR THE 1980's

The Task Force has formulated a set of actions which it considers essential to the revitalization of the laboratories. The mechanics of implementing the initiatives contained in these actions vary broadly. Several require the personal support of the Secretary of Defense, others can be placed in effect by coordinative action in the OSD and the Military Departments, and a few can be accomplished within the respective Services.

Our perspective for these actions is both short- and long-term. We are convinced that if meaningful progress is to occur, the DoD must act promptly—and with sustained intensity. If this is not done, the LMTF effort will be just another study of laboratories in a very long list of such studies. Prior studies should be the point of departure; the DoD cannot afford to repeat them. "Backsliding" is a real danger. Our proposals are oriented toward minimizing this fatal weakness.

Accordingly, we will now address each of these actions.

A wide array of barriers impede the performance of the laboratories. The LMTF confined its *initial* efforts to a select group of these barriers—primarily those considered to be particularly inhibiting but subject to reduction. These barriers fell into three groups: Personnel and Manpower (affecting the quality, quantity, and utilization of this key asset); Facilities and Equipment (affecting the inherent capability of the laboratories); and Procurement and Acquisition procedures (affecting the effectiveness of laboratory operations).



PERSONNEL & MANPOWER
• FREQUENTLY CHANGING MANPOWER CEILINGS
• HIGH GRADE REDUCTION
• SALARY COMPETITION
• TRAVEL AND TRANSPORTATION LIMITS
• INSPECTIONS AND AUDITS

Five issues have been addressed, bearing heavily on the workforce and the productivity of that workforce. For each of these issues we have identified the principal problem, impact, and corrective actions. Our recommendation correspondingly suggests who should take action. We have been deliberately precise in this matter: SECDEF means the Secretary of Defense; OSD means the Office of the Secretary of Defense; and DoD means the OSD and the relevant Military Departments.

PERSONNEL & MANPOWER

ISSUE:	• FREQUENTLY CHANGING MANPOWER CEILINGS
PROBLEM:	• SIZE, FREQUENCY AND SCHEDULING OF CHANGES
IMPACTS:	• MANPOWER TURBULENCE (SIZE AND MIX) • INEFFICIENT WORKLOAD PLANNING & EXECUTION • ADMINISTRATIVE BURDEN
ACTIONS:	• CONTINUE EFFORT TO STABILIZE DoD CEILING • DETERMINE THE IMPLICATIONS OF THE PENDING FULL-TIME-EQUIVALENT (FTE) PROCEDURES • REMAIN ALERT TO POSSIBLE CONGRESSIONAL EXEMPTIONS TO CEILINGS FOR INDUSTRIAL FUNDED ACTIVITIES
RECOMMENDATIONS:	• SECDEF CONTINUE TO SEEK STABILIZED CEILING • LMTF EXAMINE FTE IMPACTS ON LABORATORIES • OSD SUPPORT REMOVAL OF CEILINGS FOR LABORATORIES FROM INDUSTRIAL FUNDED LABORATORIES • SECDEF USE DISCRETIONARY AUTHORITY TO STABILIZE LABORATORY CEILINGS

Without doubt manpower ceiling reductions have been the greatest single factor negatively impacting the contribution of the laboratories over the past fifteen or so years. Civilian manpower allocations dominate but military spaces are equally important, particularly in the medical and Air Force laboratories.

The LMTF members expressed very deep concern about this issue, primarily from three standpoints: first, the size of reductions; second, their frequency; and third, their multiplicity. For example, the Army laboratories have been reduced in size more than one-third during the past decade; cuts have occurred every year in one form or another and are continuing; and these cuts come in several forms and at different times during each fiscal year. The turbulence and loss of effectivity caused by this agglomeration of cuts has reached truly serious proportions.

The hire-and-fire practices generally seen in industry are not available to the DoD laboratories as a means of offsetting this instability. Personnel statutes and policies, Congressional constituent interests, and pay restrictions prevent the laboratories from accommodating cuts in an effective manner. As a result the instability has become increasingly debilitating to the laboratories.

It is the opinion of the LMTF that DoD laboratories, in the aggregrate, are now at or below "critical mass" and that any further manpower reductions *cannot* be absorbed without significant negative effects on capability. Action must be taken to obtain a higher degree of ceiling stability. To the degree that this is obtained, the laboratories can institute management initiatives to more effectively meet their missions. If the cut trend is not reversed, closure of laboratories and corresponding mission and workload withdrawals quickly become the only alternative. The array of military technology areas at risk makes relief from current manpower practices an action of the highest urgency.

PERSONNEL & MANPOWER

ISSUE:
- HIGH GRADE REDUCTION FOR CIVILIAN SCIENTISTS AND ENGINEERS AND ASSOCIATED LABORATORY PERSONNEL

PROBLEMS:
- SEC 811(A) OF PL95-79 (FY79 AUTHORIZATION BILL) MANDATES DRAWDOWN
- CIVIL SERVICE REFORM ACT PL95-454 SAVE-GRADE PROVISION NEGATES USE OF DOWNGRADING TO MEET MANDATORY REDUCTION

IMPACTS:
- RESTRICTION DISTORTS GRADE DISTRIBUTION AND MIX
- ADVERSE EFFECTS ON CAREERS PROGRESSION, RETENTION, AND HIRING
- PREORDAINS POORER QUALITY LABORATORIES IN FUTURE

ACTIONS:
- REPEAL SEC 811(A) AS RECOMMENDED IN SEC 803 OF HR 6974 (FY81 AUTHORIZATION)
- MODIFY SEC 811(A) TO LIMIT OVERALL REDUCTION TO THAT ALREADY ACCOMPLISHED
- MODIFY PL95-454 TO ALLOW CREDIT FOR HIGH GRADE POSITIONS DOWNGRADED ALTHOUGH INCUMBENTS RECEIVE SAVE-GRADE
- OBTAIN EXEMPTIONS FOR GS-13'S
- CREATE DEFENSE SCIENCE AND TECHNOLOGY (S&T) SERVICE

RECOMMENDATIONS:
- SECDEF SUPPORT REPEAL OF SEC 811(A) OF PL 95-79
- OSD WORK WITH OPM TO CREATE DEFENSE S&T SERVICE

Section 811(a) of PL95-79 (the Defense Authorization Act of 1978) required the DoD to reduce the number of its civilian employees in grades GS-13 through GS-18 by two percent per year from FY78 through FY80.

The Civil Service Reform Act (CSRA) of 1978 (PL95-454) requires two year save-grade for any employees downgraded since 1 January 1977, through no fault of their own. Clearly, PL95-79 and PL95-454 run contrary in intent. During the FY80 Armed Services hearings this inconsistency became apparent to the Congress and Section 817 of the FY80 Defense Authorization Act was passed to extend the time period or higher grade reductions by one year, to FY81.

Deep concern has already been expressed to the Congress by top officials of the DoD over the impacts of high grade reduction statutes. Section 803 of HR-6974 (the FY81 Defense Authorization Bill) states: "The Committee has since received evidence that the impact of further reductions in the number of supervisory and professional civilians will be detrimental to DoD capabilities, particularly in logistic and research and development functions. For this reason, the Committee recommends the repeal of Section 811(a) that otherwise would require implementation of the final phase of the reduction in FY81."

In the area of research and development, GS-13 scientists and engineers are universally regarded as being at the journeyman level. Rationally, this group should not be considered to be in "high grade" positions. Their inclusion has resulted in striking losses within grade and, equally important, severe losses in lower graded S&E's who see no future in DoD employment.

The DoD must be able to offer adequate career opportunities and status commensurate with responsibilities if it is to retain and attract the high quality talent vital to its mission performance. The criticality of the national S&E situation justifies renewed attention to a special pay group covering defense personnel in the S&E job series, in effect, a Defense Science and Technology Service.

PERSONNEL & MANPOWER

ISSUE:
- SALARY COMPETITION

PROBLEMS:
- NEW AND RECENT GRADUATES
  - SPECIAL SALARY SCHEDULES LIMITED BY 5USC5303
  - S&E GS-5/7 ENTRY LEVELS AT MAXIMUM UNDER LAW GS-9/11 LEVEL INCLUDED BUT NOT AT MAXIMUM
- EXPERIENCED (JOURNEYMEN)
  - 5USC5333 REQUIRES APPOINTMENTS AT STEP 1
  - GS-11/18 HIRING ABOVE STEP 1 REQUIRES AGENCY HEAD AND OPM APPROVAL

IMPACTS:
- NEW AND RECENT GRADUATES – EXISTING RATES INSUFFICIENT TO ATTRACT AND RETAIN MOST S&E SPECIALITIES
- JOURNEYMEN – PROCESS NOT TIMELY (RESULTS IN ESCAPE OF CANDIDATE)

ACTIONS:
- PURSUE ACTION WITH OPM TO ENSURE REPEAL OF SALARY SCALE LIMIT IN 5USC5303
- EXPLOIT RECENTLY DELEGATED AUTHORITY UNDER OPM BULLETIN 300-52 "ADVANCED IN-HIRING RATES BASED ON SUPERIOR QUALIFICATIONS"
- RAISE GS-9/11 S&E TO COMPETITIVE LEVELS

RECOMMENDATION:
- OSD SUPPORT BOTH OF THESE ACTIONS AND WORK TO ADJUST OVERALL S&E PAY SCALE TO PROVIDE MARKET COMPETITION

In the area of science and engineering, Federal pay rates and policies are not comparable with private sector pay for the same level of work. Further action to offset this situation, as permitted by 5USC5301, is seriously lagging. Consequently, the current pay schedules significantly handicap the retention and recruitment of the well-qualified civilian technology personnel required within the DoD laboratory community.

In exercising the authority of the President under Section 5303(a) and (b) of Title 5 United States Code, the Office of Personnel Management (OPM) has issued Special Salary Rate Tables for Professional Engineers which start at the legal maximum (step 10 of basic GS schedule) for grades 5 and 7 and the lower steps of grades 9 and 11. This extension does not meet the pay comparability provisions of 5USC5301.

The 5USC5333 "(triple 3s)" requires that new appointments shall be made at the minimum rate of the appropriate grade. OPM regulations permit exceptions in cases of special need or extraordinarily high qualifications of a candidate. However, the process for obtaining this exception cannot be performed promptly and often the potential employee is lost. OPM Bulletin 300-52 provides a base for improving delegation of authority for advanced in-hiring rates based on superior qualifications. This delegation has recently been signed and must be implemented effectively to allow timely acquisition of qualified journeymen.

Personnel at GS-9 and 11 levels are not addressed adequately in existing procedures. The young scientist or engineer with limited graduate training or job experience is as vitally needed as any other level of employee. Provisions should be sought to ensure continuing comparability of pay for this group. Inequities also exist in the handling of Factor IV (man-in-the-job) situations which cry out for attention if we are to have any semblance of pay comparability for superior employees.

PERSONNEL & MANPOWER

ISSUE:
- TRAVEL AND RECOMMENDATION LIMITS FOR MISSION RELATED WORK

PROBLEMS:
- ADMINISTRATIVE TRAVEL RESTRICTED SINCE FY76 (PL94-157)
- FY80 CONTINUING RESOLUTION (PL96-86) MANDATES $500M FEDERAL TRAVEL CUT
- DoD CUT ($375M) NOW AFFECTS MISSION, TECHNICAL TRAVEL AND TRANSPORTATION OF THINGS (OBJECT CLASS 22) AS WELL AS ADMINISTRATIVE
- INHIBITS PERSONNEL TRANSFERS, EMPLOYMENT, LIAISON, TRAINING, AND SCIENTIFIC EXCHANGE

IMPACTS:
- RESTRICTIONS DIRECTLY IMPACT PROGRAM CONDUCT AND ACCOMPLISHMENT
- FORCES INEFFICIENT USE OF FUNDS AND POSSIBLE BORDER-LINE PRACTICES

ACTIONS:
- URGE CONGRESSIONAL REPEAL OF SEC 112 (PL96-86)

RECOMMENDATION:
- DoD SUPPORT ACTIONS TO REDUCE MISSION IMPACTS

Section 205 of PL94-157 (the FY76 Supplemental Appropriations Act) expressed "the sense of Congress that the President, through the Director of OMB, shall take immediate steps to restrain the inflationary impact of Federal expenditures and to conserve the use of energy by ordering a reduction of Federal travel expenditures not to exceed ten percent." In FY78, the President asked for reduction of FY79 administrative travel costs by twenty percent below the 1979 budget. PL96-86 (the continuing resolution for FY80) mandated a $500M cut across the Government.

Administrative travel has been defined in OMB Bulletin 78-18. The Senate Appropriations Committee in Report 96-393 stated that any evaluation of the amount of administrative travel that is needed to operate the defense establishment must be made separately from those categories of travel that are related to the performance of an organization mission.

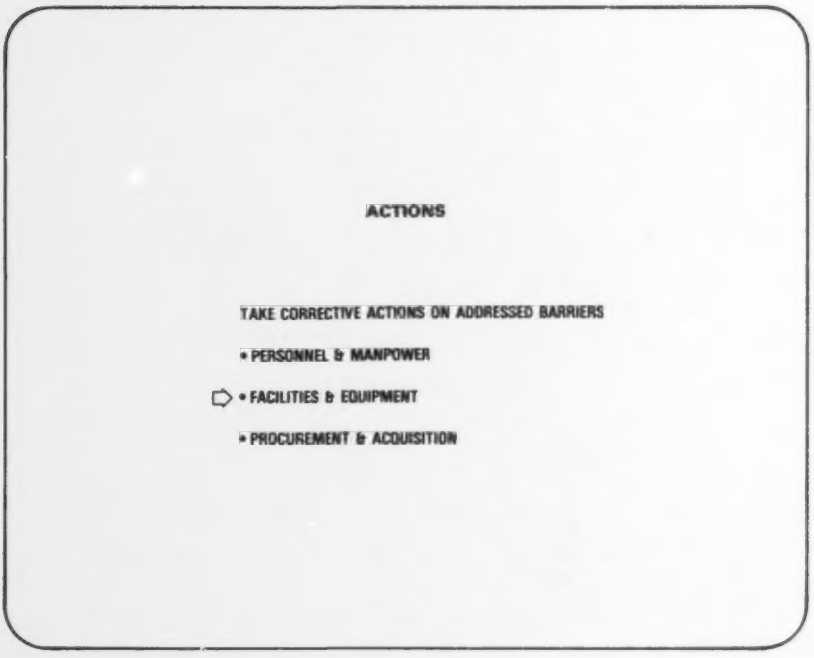
Currently, the foregoing and other travel constraints are producing gross distortions in operating procedures. Laboratory managers are being forced to stretch-the-rules in an effort to avoid technical mission impacts. Their efforts are failing; the mission work is being directly impaired. The transportation of things (object class 22) is every bit as important as transportation of people in the day-to-day operation of laboratories. There is increasing case evidence that a series of well-intended budget constraints are producing counter-productive effects to the severe detriment of the DoD.

It is essential that this situation be mitigated before the impacts become irreversible.

PERSONNEL & MANPOWER

ISSUE:	• INSPECTIONS AND AUDITS
PROBLEMS:	• REPETITIVE, OVERLAPPING, RANDOMLY SCHEDULED INSPECTIONS AND AUDITS DIVERT TECHNICAL MANPOWER FROM PRIMARY MISSION-RELATED TASKS
	• SHORT NOTICE PRECLUDES ADEQUATE PREPARATION OF RESPONSES
IMPACTS:	• DELAY IN PROGRAMS
	• INTERRUPTION OF TECHNICAL ACTIVITIES
	• DIFFICULTY IN PROVIDING ADEQUATE RESPONSES TO LEGITIMATE CONCERNS OF THE INSPECTIONS AND AUDITS ON SHORT NOTICE
	• COSTLY, INEFFICIENT, AND SEEMINGLY EXCESSIVE
ACTIONS:	• DEVELOP UNDERSTANDING WITH INVESTIGATING AND AUDITING BODIES CONCERNING SCHEDULES, DEMAND ON PEOPLE AND FACILITIES, AND PLANNED FREQUENCY AND DURATION OF VISITS
RECOMMENDATIONS:	• OSD TAKE LEAD IN DEVELOPING UNDERSTANDING WITH ITS OWN AND EXTERNAL INVESTIGATING AGENCIES
	• SERVICES DEAL WITH THE PROBLEMS ARISING FROM INTERNAL AUDITS AND INVESTIGATIONS

While little fault can be found with the concept of inspections and audits, the manner of their conduct is proving to be an increasing burden to the laboratories. This situation appears particularly bothersome for laboratories within the National Capital Region (NCR). Easy access, travel constraints, and investigator personal orientations combine to produce seeming inordinate inspections/audits of these laboratories. A not-too-different situation exists for laboratories outside the NCR. The visibility of laboratories in the RDA process probably lies at the heart of this situation. The laboratory community understands this and strives to be cooperative. However, it is being subjected to fragmented and overlapping examinations of the various functional aspects of laboratory operations. Too often, these focus on compliance with specific rules, regulations, and procedures rather than on end results and performance of the organization as a whole. Examination of the details of several such inspections/audits leads the LMTF to suggest that action be taken to secure at least a modicum of constraint and control.



Personnel and Manpower problems are, indeed, imposing. But equally commanding are concerns involving Facilities and Equipment. Without effective tools even the best technology work force can make little contribution.

FACILITIES AND EQUIPMENT

- **INADEQUATE MODERNIZATION OF LABORATORY FACILITIES**
- **INSUFFICIENT MODERNIZATION AND ACQUISITION OF LABORATORY EQUIPMENT**

The $4B investment of the DoD laboratories in facilities and equipment is rapidly becoming inadequate for effective mission performance. Some facilities, which are several decades old but which have received reasonable modernization through the years, remain highly useful. However, others have become, or are becoming, marginal in their utility. The equipment in these facilities is in a similar state. In some instances these tools are merely old; whereas, in other instances they are outdated and inadequate, not because of age but because of the rapid growth of technology and mission requirements. Some are very energy-inefficient. These facilities and equipment are an essential element of the work environment, and consequently greatly affect the productivity of the laboratories.

FACILITIES

ISSUE:
- INADEQUATE MODERNIZATION OF LABORATORY FACILITIES

PROBLEMS:
- MANY FACILITIES ARE SUBSTANDARD / INADEQUATE / OBSOLETE / ENERGY INEFFICIENT
- ADVANCING TECHNOLOGY AND NEW PROGRAMS REQUIRE APPROPRIATE FACILITIES

IMPACTS:
- INHIBITS WORK PRODUCTIVITY AND SLOWS DEVELOPMENTS
- DOES NOT ATTRACT AND SUPPORT HIGHEST QUALITY SCIENTIFIC AND TECHNICAL PERSONNEL
- REDUCES ABILITY TO PROVIDE PROGRAM AND LIFE CYCLE SUPPORT
- FACILITY CONSTRUCTION OFTEN LAGS R&D PROGRAM REQUIREMENTS

ACTIONS:
- ENSURE SIGNIFICANT MONETARY INVESTMENT IN R&D FACILITIES FOR EACH SERVICE OVER NEXT 10 YEARS

RECOMMENDATIONS:
- SECDEF AND DoD ESTABLISH A LABORATORY FACILITIES MODERNIZATION POLICY TO ENSURE REPLACEMENT OF FACILITIES IN A TIMELY MANNER SPECIFICALLY TAILORED TO THE BUSINESS VENTURE CHARACTERISTICS OF LAB SYSTEM (AS A MINIMUM, A FACILITIES MODERNIZATION PROGRAM FOR EACH SERVICE SHOULD BE ABOUT $70M EACH YEAR FOR THE NEXT TEN YEARS)
- OSD SELL THIS POLICY TO THE CONGRESS AND DoD AGGRESSIVELY MONITOR ITS IMPLEMENTATION
- IN ADDITION, DoD SHOULD SUPPORT CONSTRUCTION OF NEW FACILITIES ON A CASE-BY-CASE BASIS

Many of the facilities of the laboratories are the best in the western world. Many other facilities which once met such a criterion no longer qualify. No service remained immune from such deterioration. This decline seriously jeopardizes the ability of the laboratories to meet mission challenges.

A modest modernization program, geared not to mere replacement but to the needs of today and the anticipated future, would be a major positive step toward revitalization of the laboratories. A reasonable goal would be "replacement" of about one-half of the existing facilities over a ten year period. This could be accomplished if, considering inflation, about $200M was provided by Congress for this purpose each year during the 1980's, and if major new facilities were funded over-and-above this replacement action on a case-by-case basis. Procedurally, the initial perspective is that the general limit should be set by relation to specific plan value, over time (e.g., 10-40 years), as practiced in private sector accounting. An excellent study, which can serve as a pilot for other laboratories, was prepared by the Naval Weapons Center (NWC). This study developed a time-phased facilities modernization plan for NWC.

EQUIPMENT

ISSUE:
- INSUFFICIENT MODERNIZATION AND ACQUISITION OF LABORATORY EQUIPMENT

PROBLEMS:
- MUCH LABORATORY EQUIPMENT IS SUBSTANDARD/OBSOLETE
- ADVANCING TECHNOLOGY REQUIRES NEW LABORATORY EQUIPMENT
- GENERAL PURPOSE EQUIPMENT PURCHASES SEVERELY LIMITED
- NO EQUIPMENT RESERVE FUND

IMPACTS:
- INHIBITS WORK PERFORMANCE
- DOES NOT ATTRACT AND SUPPORT HIGH QUALITY SCIENTIFIC AND TECHNICAL PERSONNEL
- COSTLY TO MAINTAIN OLD EQUIPMENT AND WASTES MANPOWER

ACTIONS:
- ESTABLISH CHARGE SYSTEM FOR EQUIPMENT DEPRECIATION
- INCREASE 6.5 RDTE LINE BUDGET FOR EQUIPMENT
- ENSURE SIGNIFICANT MONETARY INVESTMENT IN EQUIPMENT

RECOMMENDATIONS:
- DoD MODIFY EXISTING REGULATIONS (E.G., DoDD 7410.4) TO PERMIT DEPRECIATION CHARGES AT APPROPRIATE LABORATORIES
- SECDEF AND DoD ESTABLISH A LABORATORY EQUIPMENT MODERNIZATION POLICY TO ENSURE THAT GENERAL PURPOSE EQUIPMENT IS REPLACED OR ACQUIRED (IF NEW) IN A TIMELY MANNER (WITH AVERAGE LIFE BASED ON IRS STANDARDS FOR PRIVATE ENTERPRISE)
- EACH SERVICE HAVE AN EQUIPMENT MODERNIZATION PROGRAM OF AT LEAST $25-30M EACH YEAR FOR THE NEXT TEN YEARS

The capacity and capability of a laboratory to perform its assigned roles is as much a function of its equipment as it is of people or other plant operations. The manner in which laboratories are equipped is lacking, primarily because the Services principally fund programs and do not make adequate provision for general purpose/technical equipment needs. (NOTE: the Air Force is a notable exception to this; they fund their laboratories under one line item, RDTE 6.2, and provide for costs of general purpose equipment in the process. However, this 6.2 source is limited.

The DoD, in coordination with the SECDEF, should undertake to establish general purpose depreciation procedures that will provide replacement or acquisition at an adequate rate. Included in this initiative should be a SECDEF policy similar to that recommended for facilities to ensure that the modernization rate is in keeping with the needs of the laboratories and good business practices (e.g., average life of seven years, as used by the Internal Revenue Service for private sector laboratories).

A primary role of the laboratories is support of systems acquisition. Performance of this function and associated support of direct in-house activities requires the laboratories to conduct extensive procurement and acquisition actions. Consequently, contracting procedures lie at the core of laboratory efforts and efficiency.

PROCUREMENT AND ACQUISITION

- DETERMINATIONS AND FINDINGS (D&F) LIMIT AND PROCESS
- CONTRACTING
- NEEDED IMPROVEMENTS IN LABORATORY FINANCIAL MANAGEMENT SYSTEMS

The contracting area is plagued with barriers inhibiting laboratory procurement actions. Institutional procedures are often highly complex and technical. Further, the Congress requires that contracting be one means for redressing societal ills (hence provisions to address small business, freedom of information, and a host of special interests).

Of these many constraints, three have been selected for initial consideration.

PROCUREMENT AND ACQUISITION

ISSUE:	• DETERMINATION AND FINDINGS (D&F) LIMIT AND PROCESS
PROBLEMS:	• D&F $100K LIMIT TOO LOW (D&F HAS 1962 BASE) AND APPROVAL PROCESS TOO LENGTHY
	• USED AS PROGRAM APPROVAL DOCUMENT (NOT LEGISLATIVELY INTENDED)
IMPACT:	• EXTENSIVE REVIEWS AT MULTIPLE LEVELS SIGNIFICANTLY INCREASE TIME REQUIRED FOR CONTRACT AWARD
ACTIONS:	• LEGISLATIVE CHANGES TO INCREASE THRESHOLD FROM $100K TO $1M (52% DECREASE IN ADMINISTRATIVE BURDEN AND YET ONLY 2% OF TOTAL DOLLARS CURRENTLY UNDER D&F'S WOULD NO LONGER REQUIRE SECRETARIAL APPROVAL)
	• INCREASE THE USE OF CLASS D&F'S
	• STREAMLINE PROCESS
RECOMMENDATIONS:	• OSD CONTINUE TO SEEK LEGISLATIVE CHANGES
	• DoD INTERIM MEASURE USE CLASS D&F'S WHEREVER POSSIBLE
	• DoD REDUCE INSTITUTIONAL REVIEWS TO ONE PER LEVEL

The Armed Services Procurement Act (10USC2311) requires that agency heads authorize negotiation of contracts involving more than $100,000 for RDTE work. This dollar level was enacted in 1962, replacing the $25,000 threshold established in 1948 at the inception of the Act.

The number of contracts over $100,000 has been steadily increasing as inflation has reduced the purchasing power of RDTE funds. Determination and Finding (D&F) documentation is required for contracts to perform work pursuant to 10USC2304(a)(11). Consequently, such D&F's pass through multiple review levels to receive Secretarial approval. D&F's are often complex and this staffing time becomes significant to the time needed for contract award.

By "bulking" major planned contracts into one D&F—a class D&F—the approval process can be simplified and also used to discipline early program planning. (NOTE: the Air Force has a very effective class D&F process.) Additional process streamlining could be obtained by instituting parallel coordination procedures for all but the final approval levels.

PROCUREMENT AND ACQUISITION

ISSUE:	• CONTRACTING
PROBLEM:	• MANY DoD LABORATORIES ARE IMPEDED BY LACK OF DEDICATED CONTRACT SUPPORT, LIMITED IMPREST FUND AUTHORITY, LIMITED ACQUISITION AUTHORITY, AND REQUIREMENT TO FOLLOW MAJOR SYSTEM PROCUREMENT FOR NON-MAJOR CONTRACTING
IMPACTS:	• UNACCEPTABLY LONG LEAD TIMES FOR PROCESSING CONTRACTS • SERIOUS DELAYS IN RECEIPT OF SUPPLIES AND SMALL PURCHASES • IMPREST FUND LIMIT DENIES OPERATIONAL FLEXIBILITY • INSUFFICIENT AUTHORITY AT LABORATORY LEVEL TO PROCESS BULK OF CONTRACTUAL WORKLOAD
ACTIONS:	• CHANGE POLICIES TO PROVIDE FOR ADEQUATE CONTRACTING AUTHORITY AND SMALL PURCHASE SUPPORT WITHIN LABORATORIES • RAISE DOLLAR VALUE OF IMPREST FUND AUTHORITY FROM $150/300 TO $300/700
RECOMMENDATIONS:	• DoD PROVIDE DEDICATED R&D CONTRACTING ACTIVITIES FOR LABS • OSD INSTRUCT DEFENSE ACQUISITION REGULATION (DAR) COMMITTEE TO AMEND DAR IMPREST FUND THRESHOLDS • DoD INCREASE SMALL PURCHASE FLEXIBILITY & CONTRACTING AUTHORITY

This initiative addresses several individual but somewhat overlapping problems. One particular barrier to effective laboratory contracting is the lengthening lead times on material and services being procured through consolidated/base/regional contracting offices. This centralization of procurement functions causes work stretch-outs, missed opportunity windows, reduced technological development, and—as a result of frustration—attrition of talented scientists and engineers from the laboratories. The most serious aspect of the problem overall in the laboratory community, is in the small purchase category ($10,000 or less). The impact of constraints associated with small purchases is greatest in the technology base. Equally important is the limitation of contract authority at some laboratories (particularly in the Navy).

Imprest fund thresholds have not kept pace with inflation. Defense Acquisition Regulations (DAR) need revision.

PROCUREMENT & ACQUISITION

ISSUE:
- NEEDED SPECIAL FINANCIAL MANAGEMENT SYSTEMS FOR LABORATORIES

PROBLEMS:
- INDUSTRIAL FUNDING, ALTHOUGH A GENERALLY EFFECTIVE FINANCIAL SYSTEM, DOES NOT ADEQUATELY ADDRESS BARRIERS SUCH AS:
  - RATE STABILIZATION
  - INCREMENTAL FUNDING
  - CONTINUATION OF WORK AT THE BEGINNING OF A NEW FISCAL YEAR
  - MULTIPLE FUNDED CUSTOMER ORDERS
  - FRAGMENTATION OF FUNDING
  - COMMITMENT AND OBLIGATION LEGAL LIABILITIES

IMPACTS:
- DELAYS IN WORK ASSIGNMENT
- LOSS OF PERSONNEL PRODUCTIVITY
- UNFAIR CHARGES TO CUSTOMERS
- IMPRECISE "REAL COST" ANALYSES
- MICRO FISCAL CONTROL SERVING LITTLE USEFUL PURPOSE

ACTIONS:
- ESTABLISH A "SERVICE FUND" APPROACH FOR SELECTIVE USE
- APPLY TO ALL INDUSTRIALLY FUNDED LABORATORIES (ARMY AND NAVY)

RECOMMENDATIONS:
- DoD USING NAVY SERVICE FUND STUDY AT A POINT OF DEPARTURE ESTABLISH AND IMPLEMENT THE SERVICE FUND CONCEPT

The original intent of Industrial Funding in DoD was slanted toward commercial/industrial activities such as depot-level maintenance facilities (e.g., shipyards, aircraft re-work facilities). Currently, OSD policies and procedures for managing such activities often do not fit R&D activities but cause laboratories operating under the industrial fund to confront constraints which, in many cases are counterproductive.

All Navy laboratories (except medical) operate under the industrial funding concept. About one-fifth of the Army laboratories are under industrial funding. The Air Force tried industrial funding at one activity some years ago, did not like it, abandoned it, and now uses "Block" institutional funding. The industrial funding concept gives R&D activities three useful management tools: (1) a working capital fund, (2) a cost accounting system, and (3) a "buyer-seller" relationship between the laboratory and its customers, with charging of all allowable costs (e.g., direct, cost center overhead, general, and administrative expenses) to the specific benefiting users.

One alternative to industrial funding for (Navy) laboratories is the Resources Management System (RMS). One major drawback of the RMS is that it does not provide a working capital fund, a device particularly useful for laboratories.

The Navy has conducted a preliminary study of a modified system which is termed "Service Fund." This system builds upon the flexibility provided in 10USC2208, which provides for "commercial-type" activities as well as industrial-type activities. The establishment of a separate set of procedures under the umbrella of "commercial-type" activities could better provide for the working capital needs of laboratories. Such an approach avoids dilution/change to existing industrial fund policies and regulations and can be adopted by any Service as a stand-alone financial management system if the Service and OSD concur.

ESSENTIAL ACTIONS

- TAKE CORRECTIVE ACTIONS ON ADDRESSED BARRIERS
- CONTINUE WORK TO IDENTIFY AND ADDRESS REMAINING BARRIERS
- ADOPT SELECTIVE APPLICATION PRINCIPLE FOR LABORATORIES
- PROVIDE FOLLOW-THROUGH ACTION AT OSD AND SERVICE LEVELS
- MONITOR PROGRESS
- ASSESS LABORATORIES VITALITY OVER TIME

LABORATORIES
ACTION AGENDA
FOR THE 1980'S

In addition to the barriers addressed in detail thus far, the LMTF also identified a lesser group of concerns. Several representative concerns are shown for the primary barrier areas on the next three charts. It is the intent of the LMTF to continue its work by addressing these and other yet to be identified concerns, to better ensure that intensive management attention is given to all barriers significantly inhibiting the vitality of the DoD laboratories.

PERSONNEL & MANPOWER
OTHER CONCERNS

- OVERTIME CONTROLS
- CEILING ON EMPLOYMENT IN NATIONAL CAPITAL AREA
- SES / MERIT PAY APPRAISAL TIMING – DoD PERIOD OF 1 JULY – 30 JUNE IS NOT COINCIDENT WITH 1 OCTOBER – 30 SEPTEMBER FISCAL YEAR

FACILITIES AND EQUIPMENT

OTHER CONCERNS

- RAISE LIMIT ON LOCAL APPROVAL FOR USE OF RDT&E FUNDS FOR FACILITIES FROM $100K TO $500K FOR APPROPRIATIONS AVAILABLE FOR OPERATION AND MAINTENANCE
- AMEND 10 U.S. CODE 2353 TO PERMIT THE SAME DEGREE OF FREEDOM TO BUILD FACILITIES IN-HOUSE AS AT CONTRACTORS

PROCUREMENT & ACQUISITION
OTHER CONCERNS

- NEED FOR MULTIPLE YEAR FUNDING OF TECHNOLOGY BASE CONTRACTS
- LACK OF DIFFERENTIATION BETWEEN TECHNOLOGY BASE AND MAJOR PROCUREMENT PRACTICES
- NEED FOR STREAMLINED NEGOTIATIONS

ESSENTIAL ACTIONS

- TAKE CORRECTIVE ACTIONS ON ADDRESSED BARRIERS
- CONTINUE WORK TO IDENTIFY AND ADDRESS REMAINING BARRIERS
- ADOPT SELECTIVE APPLICATION PRINCIPLE FOR LABORATORIES
- PROVIDE FOLLOW-THROUGH ACTION AT OSD AND SERVICE LEVELS
- MONITOR PROGRESS
- ASSESS LABORATORIES VITALITY OVER TIME

KEY–ISSUANCE OF:
DoD
LABORATORIES
ACTION AGENDA
FOR THE 1980'S

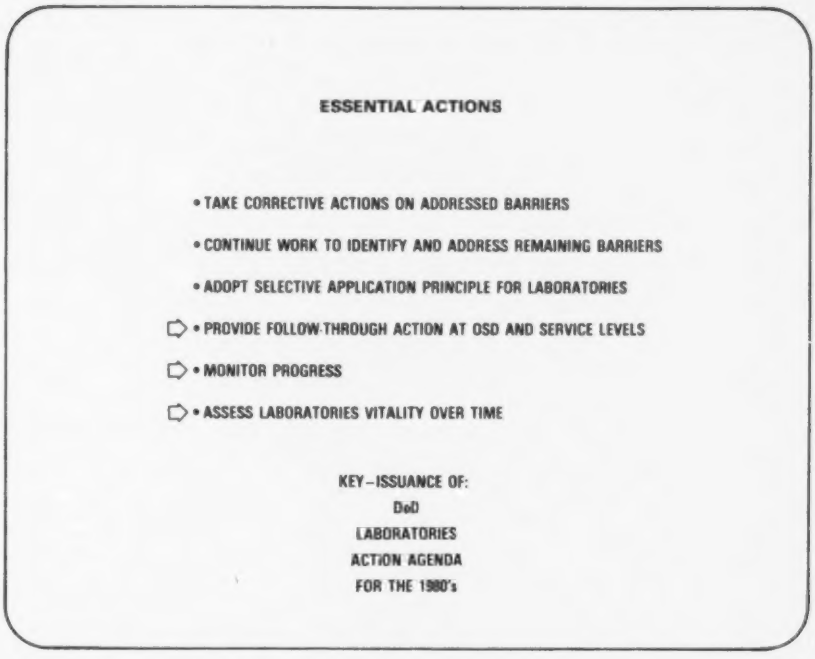
The current constraints on personnel and dollar resources in the face of readiness, modernization, and sustainability needs, places the Services in a series of dilemmas. The requirement to constantly choose between unsatisfactory alternatives is particularly apparent in the Service materiel communities. Senior management must balance R&D, procurement, logistics, maintenance, and a host of other functions to achieve even the semblance of a coherent whole. The choices are tough and rarely palatable. Understandably, these managers are hesitant to "favor" one function at the "expense" of any other. Further, short-term urgencies tend to work against actions supportive to the laboratories multiple roles.

However, the challenge and the urgency are upon us. We see the Soviets entering the decade of the 1980's with a commitment to compete in *quality* with U.S. weapon systems. They have already made a major start in that direction, with the acceptance of the high cost in personnel, facilities, and weapons implied by this commitment. That they plan to continue this emphasis into the 1980's is clear.

The challenge to us is formidable. The LMTF is convinced that the DoD must make a major change in its management of defense technology if we are to maintain a superior technological base, and a competitive and productive industrial and academic team. In order to do this, we recommend that a principle of selective application be instituted in the DoD, with initial application on critical laboratory issues. We believe that this Principle, applied selectively, offers great leverage—a few relatively small changes, in the right places, at the right time, can greatly help to ensure the vitality of DoD laboratories. We believe that this Principle can be applied consistently through the early 1980's without jeopardizing other vital DoD functions and without serious intrusion on the prerogatives of the Military Departments. The Selective Application Principle is set forth in the next slide.

SELECTIVE APPLICATION PRINCIPLE

THE DoD LABORATORIES ARE A KEY AGENT IN ENSURING EFFECTIVE DEFENSE-ORIENTED TECHNOLOGY PROGRAMS. PRIMARY EFFORTS MUST BE FOCUSED ON IMPROVING MANAGEMENT OF OUR SCIENTIFIC AND TECHNOLOGICAL RESOURCES AND ON EXPANDING OUR TECHNOLOGICAL OPTIONS. ACCORDINGLY, THE OSD AND THE MILITARY DEPARTMENTS WILL ADOPT THE PRINCIPLE OF SELECTIVE APPLICATION TO LABORATORIES OF POLICIES AND PROCEDURES WHOSE RIGID APPLICATION INHIBITS EFFECTIVE PERFORMANCE OF ESSENTIAL LABORATORY ROLES. THIS AD HOC POLICY SHALL BE A PRINCIPLE MEANS FOR PROVIDING SIGNIFICANTLY INCREASED AUTHORITY AND FLEXIBILITY TO LABORATORY MANAGEMENT.



ESSENTIAL ACTIONS
• TAKE CORRECTIVE ACTIONS ON ADDRESSED BARRIERS
• CONTINUE WORK TO IDENTIFY AND ADDRESS REMAINING BARRIERS
• ADOPT SELECTIVE APPLICATION PRINCIPLE FOR LABORATORIES
• PROVIDE FOLLOW-THROUGH ACTION AT OSD AND SERVICE LEVELS
• MONITOR PROGRESS
• ASSESS LABORATORIES VITALITY OVER TIME
KEY–ISSUANCE OF:
DoD
LABORATORIES
ACTION AGENDA
FOR THE 1980's

Follow-through, monitoring, and assessment are inherent steps to the resolution of barriers. Considerable attention has been given to these steps by the LMTF. The details of these deliberations will not be given here because of their complexity. The following three slides summarize the intent of each action step.

57-279 O - 87 - 39

FOLLOW-THROUGH

THE APPROVED LABORATORY RESOURCE MANAGEMENT PLANS OF THE SERVICES PROVIDE A BASE FOR FOLLOW-THROUGH WITHIN EACH SERVICE. THESE PLANS ADDRESS SPECIFIC MANAGEMENT CONCERNS TO WHICH THE LMTF INITIATIVES APPLY. THE LMTF WILL IDENTIFY CONTINUING ISSUES AND WORK THROUGH DoD MANAGEMENT TO ACHIEVE THESE CHANGES THAT CANNOT BE WORKED BY THE SERVICES.

MONITORING

THE LMTF WILL SERVE AS A DoD BODY FOR PROGRESS REVIEW. IT WILL ASSESS SPECIFIC PROGRESS IN REMOVAL OF BARRIERS TO EFFECTIVE MANAGEMENT IN THE DoD LABORATORY SYSTEM AND ENCOURAGE THE MILITARY DEPARTMENTS TO SIMILARLY MONITOR SERVICE-UNIQUE ACTIONS.

ASSESSMENT

ASSESSMENT WILL TAKE TWO FORMS:

- INDIVIDUAL LABORATORIES WILL BE ENCOURAGED TO PERFORM SELF-ASSESSMENTS OF THE IMPACT OF BARRIER REDUCTION ON THEIR EFFECTIVENESS. THE LMTF WILL PROVIDE GUIDELINES TO ASSIST THIS SELF-ASSESSMENT
- THE LMTF MEMBERS WILL CONDUCT SELECTED ASSESSMENTS TO DETERMINE IF CORRECTIVE MEASURES ARE EFFECTIVE--AND FOCUS ATTENTION UPWARD THROUGH OSD AS WELL AS DOWNWARD TOWARD THE LABORATORIES

ESSENTIAL ACTIONS

- TAKE CORRECTIVE ACTIONS ON ADDRESSED BARRIERS
- CONTINUE WORK TO IDENTIFY AND ADDRESS REMAINING BARRIERS
- ADOPT SELECTIVE APPLICATION PRINCIPLE FOR LABORATORIES
- PROVIDE FOLLOW-THROUGH ACTION AT OSD AND SERVICE LEVELS
- MONITOR PROGRESS
- ASSESS LABORATORY VITALITY OVER TIME

⇨ KEY–ISSUANCE OF:
DoD
LABORATORIES
ACTION AGENDA
FOR THE 1980's

Much of the DoD laboratories scene is excellent and promotes defense capability. However, to an increasing extent, the quality and vigor of life in the laboratories is diminishing. Restoring the quality of the laboratories is a partnership problem. The LMTF has recommended, and will continue to seek out, steps which are necessary to improve the present and anticipated situation. The OSD and the Military Departments can do much to make the system work better. The laboratories themselves must work even harder to explore ways to make the system more effective. The private sector also shares in closing the gulf. If any element is stereotyped as "good guys" while others are branded as "bad guys" the whole process will suffer.

There are many points of friction; many gaps in understanding. Some are documented; some are rumor. An apparently inexorable tide of bureaucracy and sub-optimized interest seemingly engulfs the situation. Positive action is an imperative. As a step in this direction, the LMTF offers a DoD Laboratories Action Agenda for the 1980's, to encourage in a formal way, imaginative action at every level of the DoD. We must work together more intensively for our common good. Now is the time to act.

DEPARTMENT OF DEFENSE
WASHINGTON, D.C.

STATEMENT OF PRINCIPLES FOR DEPARTMENT OF DEFENSE RESEARCH AND DEVELOPMENT LABORATORIES

The guiding goal for the Defense laboratories is to achieve and maintain a level of technological supremacy that enables the United States to develop, acquire, and maintain military capabilities needed for national security. These Centers-of-Excellence complement universities and industry as a vital resource of the Nation.

OBJECTIVES

Mission

- Ensure the maintenance and improvement of national competence in areas of technology essential to military needs; avoid technological surprise.

- Maintain a continuity of effort, free from excessive commercialization pressure, directed toward the conception and evolution of advanced military materiel.

- Pursue technology concepts through the planning, programming, and budgeting process for support of direct in-house work and for potential contract placement, monitoring, and assessment.

- Provide material acquisition and operating system support.

- Have available a fast-reaction capability to solve critical, immediate technical problems that arise when unexpected operational situations are encountered.

- Stimulate the use of prototypes to mature and exploit U.S. and allied technologies.

- Carry out activities having extraordinary risk or requiring intensive resource investment not available from the private sector.

Operations

- Respond to national defense needs by undertaking actions to—
  - — Achieve timely improvements in materiel systems
  - — Reduce manpower and skill constraints on material performance
  - — Lower production, operation, and support costs for materiel
  - — Extend life of operational systems
- Continue intensive user-developer interfacing to—
  - — Achieve greater sensitivity to potential combat requirements
  - — Integrate technological objectives with materiel readiness, modernization, and sustainability requirements
  - — Evolve effective balance between technology push and requirements pull

- Continue a vigorous partnership with industry and the academic community
- Distribute efforts appropriately across short-, mid-, and long-term horizons
- Participate actively in the overall Defense planning process

Management

Provide laboratory management with the responsibility, authority, and flexibility to manage laboratories and technical programs through use of broad guidelines and without overlapping controls.

- Ensure Competency of *Personnel*
  - — Recognize clearly that the most valuable resources of the laboratories are the capability, skill, and creativity of their personnel
  - — Provide for personnel stability, challenging work, and meaningful incentives
  - — Provide for equal opportunity for development, training, promotion, recognition, and reward
- Upgrade *Facilities and Equipment*
  - — Remove limitations which constrain modernization of laboratories
  - — Promote productivity, energy efficiency, and cost avoidance through policies that modernize facilities and equipment
  - — Base replacement policies on practice that befits the business venture nature of research and development activity
- Provide Effective Procedures for *Procurement and Acquisition*
  - — Provide laboratories with the authority to make procurements and acquisitions in a timely and efficient manner
  - — Ensure technical excellent in performance
- Achieve Continuing *Assessment and Accountability*

The Office of the Secretary of Defense and Military Departments will be jointly responsible for establishing policies and procedures which are conducive to the continuing vitality of the laboratories. Accordingly, periodic evaluations will be conducted to assess the health of the laboratories, the quality and quantity of their contributions, and their performance against the public's legitimate expectations of efficient and effective use of personnel and dollar resources.

SYNOPSES OF SERVICE LABORATORY RESOURCE MANAGEMENT PLANS

In accordance with the memorandum of the Secretary of Defense establishing the DoD laboratory management task force, the Military Departments developed draft plans addressing the management of their laboratory resources. These plans are clear evidence that the services recognize the urgency of maintaining effective laboratories. The plans provided identification of the respective laboratory roles. They reflected deep concern for issues involving manpower size and mix, facility and equipment adequacy, and selected institutional procedures. These plans provide a base for follow-through on the LMTF proposed initiatives.

(See attached Synopses of Army, Navy, and Air Force Plans)

SYNOPSIS OF: ARMY LABORATORIES MANAGEMENT PLAN EXECUTIVE SUMMARY MARCH 1980

The Summary provides top-down insight into the Army's perspectives on management of its laboratories. The Plan contains a host of innovative actions, some on-going, some yet to be addressed, aimed at a single issue—how can/will the Army increase the effectiveness of its manpower and dollar expenditures for laboratories. Clearly, the Army fully recognizes the need to revitalize its laboratories and has developed dynamic approaches for achieving this goal. The Army has an action agenda for the 1980's which is challenging and hard-hitting. As this Plan matures and is implemented in its details, considerable improvement in the vitality of Army laboratories should surely result.

1. The Summary addresses a broad array of factors essential to the effective mission performance of the Army in-house laboratories. It achieves three primary aims:

a. Provides a detailed basis for ensuring a current understanding of the roles of Army laboratories and recognition of their relationship to other Army functions.

b. Summarizes representative issues critical to the vigor of these laboratories.

c. Highlights approaches the Army is using to further intensify management of its laboratories. The Summary is organized to provide top management with focused information in selected areas. Resource breakouts are kept to a minimum. Individual laboratories are not discussed. A fundamental thrust of the Army Plan is to minimize formal report actions with the intent of achieving a living, breathing environment conducive to dynamic planning and vigorous contributions by the laboratories.

2. The Summary clearly provides for Army action to address four concerns:

a. Better ensuring the relevance of the work in the laboratories.

b. Improving facilities and staff.

c. Uplifting the quality of technical leadership and management in the laboratories.

d. Ensuring leadership improvements in the authority and flexibility to effectively manage laboratory resources.

3. A profile of the Army's 34 formally recognized military laboratories is given and their aggregate roles are undisputedly specified. The Summary views issues affecting Army laboratories in three segments:

a. Image

b. Operations

c. Long-term perspectives

Representative problems associated with these segments are itemized.

4. The Army Summary addresses these concerns and issues with two highly action-oriented interrelated thrusts:

a. A perspective structure encompassing the elements critical to effective management of its laboratories by the Army.

b. A participative Research, Development, and Acquisition (RDA) planning process and product to provide general and specific RDA direction to the laboratories through the next two decades and to provide a base against which their individual and collective needs and contributions can be "measured."

5. The perspective structure provides for analyses of the posture of Army laboratories in four areas:

a. Need

b. Capability

c. Performance

d. Planning/Plan

This perspective provides an excellent approach for integrating the Army laboratories with the Total Army.

6. The dominant thrust for achieving this integration is a Long-Range RDA Plan/Investment Strategy. The Summary is supported by an extensive Appendix outlining the Army's actions to achieve this Plan. Review of the Appendix reveals a host of actions directed toward the development and maintenance of a stable Long-Range R-A Plan responsive to total Army capability needs and opportunities. Initial actions have already significantly influenced the Army's POM 82-86 preparation. The first formal Long-Range RDA Plan is targeted to assure responsive Science and Technology, Systems Development, Product Improvement, and Procurement Plans for integration into the POM 83-87 including the Extended Planning Annex for FY88-89. Summary of the Appendix follows.

7. The Army Summary also provides a basis for addressing the four concerns mentioned in paragraph 2 above. This set of over twenty initiatives is focused on specific areas for laboratory improvement and, in the aggregate, they cover the spectrum of matters appropriate for Army attention.

SUMMARY OF APPENDIX ON LONG-RANGE RDA PLANNING

Intensive attention is being given to improving Army long-range RDA investment strategy. Appropriate steps are being taken by the Army Secretariate, DA Staff agencies and offices, and user and developer field organizations. An attitude of urgency and realism is clearly evident.

The dominant thrust is one of mission-orientation. This approach reflects responsiveness to the direction of the Congress, Office of Management and Budget, and Office of the Secretary of Defense, requiring that Army needs and program objectives be expressed in mission terms. The long-range RDA planning actions are being conducted with coordinative attention to major related planning in OSD and the other Military Departments. For example, close contact is being maintained with the Long-Range Research and Investment Planning Program recently initiated by the Deputy Secretary of Defense and the Under Secretary of Defense Research and Engineering.

Although operating on the premise that long-range RDA planning must be conducted as a continuum, direct action has been taken to interface with the PPB System. Significant inputs were integrated with the FY82-86 POM and action is underway to impact POM 83-87.

Two goals have been proposed by the ASA(RDA) as targets for RDA attention:

— Fielded technological equivalence by 1985.

— Fielded technological superiority in the 1990's.

These goals have been well received by the RDA community and are becoming effective driving thrusts. Direct participation from independent sources has been sought and is being provided. For example: the Army Science Board devoted its Summer Study to RDA planning and the American Defense Preparedness Association conducted a two-day symposium for industry and international representatives on Concepts and Requirements for Army Weapon Systems.

Recent emphasis on long-range RDA planning has resulted in important improvements in user-developer interaction on a mission basis. This improved dialogue will better ensure that mission needs are correlated with realistic doctrinal, organizational, and technological alternatives. The planning approach includes the development of Mission Area Analysis and Mission Area Science and Technology Plans by joint user-developer teams. This work is providing improved focus on:

— Battlefield Shortfalls

— Battlefield Opportunities

— Technological Opportunities

Specific actions are being directed to provide a dynamic but stable long-range 15-year RDA planning process with a product in a form usable by top management. Present efforts are strongly oriented to establishing the process, but it is fully recognized that the ultimate goal includes a workable product. To the maximum extent practicable, on-going Phase I MAAs and S&T Plans were available to assist in preparation of the POM 82-86. Phase II MAAs and responsive S&T Plans will be completed prior to the POM 83-87, and integrated into a formal Long-Range RDA Plan.

The Army has identified a shortcoming in its RDA process and taken corrective action. Until recently RDTE funds could not be expended for Product Improvement until a system was type classified. Action has been taken to remove this constraint and to initiate a concept of Block Design Product Improvements which offers the opportunity to field systems with overlap and thereby achieve technology insertion and better protection of the material investment.

There is good recognition of the deficiencies in the status of current long-range RDA planning and assertive action to institute steps to achieve the necessary levels of improvement. The Army laboratory communities (material, medical, engineer, and personnel) are all working to provide imaginative inputs to the Long-Range RDA Plan and to respond to the work thrusts resulting from the long-range planning process.

NAVY LABORATORY RESOURCE PLAN
DRAFT, MARCH 1980
A SYNOPSIS

The Navy Laboratory Resources Plan covers the 8 Chief of Naval Material-Commended Laboratories, the Naval Research Laboratory, the Naval Oceanographic Research and Development Activity, and the Naval Civil Engineering Laboratory. These are the major Navy Laboratories. Not covered in this plan are Navy Medical Laboratories and RDTE Activities that are attached to the Naval Material Command Systems Commands. The Navy Laboratories covered in this plan have the following characteristics:

— Full-spectrum laboratories (6.1) — Procurement-Operations & Maintenance

— Industrially funded

— Preponderantly civilian work force

— Relatively large (greater than 1000 people)

— Strong orientation to naval platform and mission

— 70% total (about 50% tech base) funds are passed through to industrial contractors

— Major components of the Navy Acquisition Process

— Federation of closely cooperating activities

The Navy Laboratory Resources Plan details the Navy's corporate approach to effective use of available R&D resources. The greatest common concern in the Navy Laboratories centers about the problems of maintaining the technical excellence and diverse capabilities under conditions that make it increasingly difficult to recruit and retain highly qualified people.

The plan summarizes recent technical achievements of the Navy Laboratories in tech. base, development, procurement, and fleet support categories.

Roles, missions, and management of Navy R&D Centers.

— Continually assessed in view of continuing changing environment

— Anticipate long-range impact of Federal Policies (A-76, A-109)

  — Transfer of additional work to private sector

  — Industrial involvement at early stages of acquisition process

— Objective for Navy to remain a sophisticated buyer, to continue to improve management of Navy acquisition, to maintain a quick-reaction RDTE capability

— Above requires strong, in-house, hands-on R&D effort to attract competent scientists and engineers

— There are management problems that are associated with initiation, termination, and transfer of technological effort, e.g., tech. base to development

— Navy laboratories are aggressively implementing Senior Executive Service and CSRA-78 and are oriented to management by objectives

Technology base is vital to systems acquisition and support; in-house capability in the Navy is eroding—coupled with the shift of laboratory manpower to non tech. base, and non-RDTE funded efforts. Reversing these trends is essential to maintaining the integrity and vitality of the Navy laboratories.

Navy Laboratory Centers are providing more support to Program Management Offices in System Development. Efforts are being aligned with the technology base so as to provide efficient transition up the development chain. Such alignments reverse an earlier trend to minimize the laboratory contribution in Systems Development.

Achieving proper balance among the tech. base, system acquisition, and fleet support remains a challege to management at the individual laboratories—a challenge that is underscored by the erosion of the tech. base work mentioned above.

The prospect of real growth in Navy R&D presents something of a dilemma to Navy Laboratory managers. Because of personnel ceilings it has become necessary to rely increasingly on industry to absorb additional laboratory work loads. Further increases in contracting out could result in changing the basic characteristic of laboratory operations with the attendant losses of competent scientists and engineers.

Industrial funding exacerbates the rate at which imbalances among the various categories of work—tech base, advanced development, fleet support, etc.—arise. The reexamination of the applicability of current industrial funding practice is very important to the Navy Laboratory System.

The tendency toward centralization in procurement, contracting, and even in providing automatic data processing equipment has resulted in excessive time and effort in justifying and defending new ADP procurement and applications. All this is in the face of the repeated demonstrated fact that productivity of R&D centers can be further increased by new and imaginative uses of the latest available ADP. The Navy has prepared a Five Year ADP Plan.

PERSONNEL RESOURCES

— Most important single class of resource

— Predominant concern

— Serious erosion of morale and of quality professional work force results from recent history of freezes, ceilings, reductions in force, and other factors tending toward instability.

— The NOSC-NWC Personnel Management Demonstration Project that begins in 1980 is a major initiative in using new approaches to job classification assignments, pay, and incentives to bring about major improvements in the ability to recruit, retain, and utilize high quality professionals.

— Navy R&D Centers are attempting to improve utilization of military personnel although, since their quest is for operationally experienced R&D-oriented project personnel, the R&D Centers are in competition with each other.

This is the Navy Laboratory Resource Management Plan response to the DoD Laboratory Task Force Initiatives to Resource Barriers to Effective Management:

— Working Groups of the DoD Laboratory Management Task Force identified issues in the various fields of personnel, procurement and acquisition, and military construction and facilities. The Navy Plan comments on these issues have been summarized above.

— The Navy Plan amplifies and addresses the issues and sets out conclusions, recommendations, and action alternatives to mitigate the problems that are identified.

— The Navy members of the DoD Laboratory Management Task Force Working Group are working with the Army, Air Force, and OSD counterparts to revise directives and authorities where applicable to prevent corrective actions.

— Through the Navy Laboratory Corporate Plan the Director of Navy Laboratories promulgates corporate goals, objectives, and initiatives on an annual basis.

— Management profiles on the component Navy Laboratories are provided in the Navy Laboratory Resource Plan.

AIR FORCE LABORATORY RESOURCE PLAN
31 MARCH 1980
A SYNOPSIS

- The Air Force Laboratory Resource Plan projects laboratory programs and the resources necessary for program implementation.

- Noting that availability of resources is a necessary but not sufficient condition for program success, the Air Force Laboratory Resource Plan describes briefly the effects that some constraints and barriers to effective laboratory management, that have been addressed by the DoD Laboratory Management Task Force, are having on the Air Force in the performance of the technology mission, and on the vitality of the laboratories.

- The Air Force Laboratories receive about 75% of their funding from the Director of Science and Technology at Air Force Systems Command Headquarters. Laboratory programs are organized along Technology Program Objective lines. The Air Force plans for 10% real growth each year in basic research and 5% real growth per year in exploratory development. Military personnel comprise about 30% of the technical work force—a much higher fraction than is found in the Army and Navy Laboratories. Salaries for military personnel are not included in laboratory budgets; but civilian salaries are. Air Force Laboratories are not industrially funded.

MANAGEMENT

Constraint Effects on the Air Force Laboratories (categories are those of the DoD Laboratory Management Task Force):

- Personnel
  - — Civilian ceilings are acceptable if somewhat constraining
  - — Air Force Laboratories operate under stable personnel authorizations
  - — Salary comparability a concern—Air Force Laboratories affected by salary structure and its resultant effect on recruitment and retention of quality people
  - — Low promotion potential contributes to loss of work force quality
  - — Must create personnel environment comparable to that existing in other R&D activities
- Military Construction and Facilities
  - — Obsolescence of facilities and equipment and the need for new research capabilities present increasingly severe problems for the Air Force Laboratories
  - — Changing technology missions of Air Force Laboratories not adequately supported
  - — Corrective action required to prevent unacceptable erosion of Air Force Laboratory capabilities
- Procurement and Acquisition
  - — Thresholds for requirement of Secretarial Determinations and Findings (D + F) and for imprest funds overly restrictive due to inflation
  - — Results in increased delays and paperwork

— Purchase from imprest funds similarly affected

— Procurement and acquisition problems in laboratories exacerbated by

  — Absence of dedicated R&D buyers

  — Imposition of standard supply procedures for R&D purchase orders

— Above all present barriers to effective management of laboratory programs.

THE SECRETARY OF DEFENSE
Washington, D.C. 20301

MEMORANDUM FOR SECRETARIES OF THE MILITARY DEPARTMENTS
UNDER SECRETARY OF DEFENSE FOR RESEARCH AND ENGINEERING
ASSISTANT SECRETARY OF DEFENSE (COMPTROLLER)
ASSISTANT SECRETARY OF DEFENSE (MANPOWER, RESERVE AFFAIRS AND LOGISTICS)
DIRECTOR, DEFENSE ADVANCED RESEARCH PROJECTS AGENCY

SUBJECT: DoD Laboratory Management

The quantity and quality of military systems being fielded by the Soviets demand improved management of our scientific and technological resources, to expand our technological options.

Last year, the Deputy Under Secretary of Defense for Research and Engineering (Research and Advanced Technology) initiated an inter-Service review, to identify institutional barriers on the DoD Laboratories' ability to accomplish their missions. The review identified a number of barriers to effective laboratory management that limit the efficient use of our resources.

I would like each Service to develop a laboratory resources plan for each lab, that provides for increased management authority to utilize more effectively personnel and fiscal resources. Plan should include a means for the continuing evaluation of managerial use of the flexibility and latitude provided. These plans should be completed by the end of March, 1980 and submitted to the Deputy Under Secretary of Defense for Research and Engineering (Research and Advanced Technology) for approval. Upon approval, unnecessary administrative restrictions upon the exercise of managerial discretion should be removed from the laboratory operations. I intend this action to establish reasonable boundaries for laboratory management's discretionary use of resources.

I am establishing a DoD Laboratory Management Task Force, chaired by the Deputy Under Secretary of Defense for Research and Engineering (Research and Advanced Technology), to oversee our continuing efforts toward improving the vitality of our laboratories. An important function of this Task Force will be to review and approve the Service plans and take the necessary follow-up action to achieve our goals in this vital area. I would like each addressee to nominate a principal and at least one working level representative to the Task Force by mid-October, 1979.

Harold Brown

EXECUTIVE SUMMARY

On 3 September 1981, Dr. Richard Delauer, Under Secretary of Defense for Research and Engineering, established a review of Department of Defense laboratories. This review was undertaken by Dr. Robert Hermann, under the direction of Dr. Robert Cooper, with the assistance of representatives of the Army, Navy, Air Force and DARPA.

The study team found:

- There is indeed a strong and continuing need for the DoD to maintain the Laboratories and R&D centers.

- Much good work is being done in the laboratories and technology created by the laboratories continues to make its way into the operating forces.

- There really are several fundamental problems involving laboratory performance and laboratory relationships with the ultimate user community.

- There exists a disconnect between the laboratories and the Operating Forces which exacerbates the problem of technology transition to the field.

- Industry, the laboratories, and the user community all feel cheated by the existing process.

- The time is ripe for improving the DoD/University R&D connection.

- There are new technology opportunities and technology based operational functions, which have evolved in recent years, which require special DoD attention to realize the maximum benefit.

- The technology environment surrounding the laboratories has dramatically changed in recent years, which requires that DoD and the Services reassess the laboratories' roles and missions.

The study team recommends:

- That the USDRE initiate action to upgrade laboratory personnel practices. Special recommendations are included in the report.

- That the USDRE support initiatives to streamline the procurement process, which is viewed as a major deterrent to the laboratories' efficient operation and innovation process.

- That the DoD modestly increase the rate of modernization of facilities ($70M per year per Service for the next 10 years) and equipment ($25-30M, per service per year for the next 10 years).

- That the USDRE support the goal of improving the DoD/University connection (six individual recommendations are included).

- That the USDRE support the establishment of an External Advisory group for each laboratory.

- That the USDRE support the establishment of an outside, expert review process which would assess each laboratory's effectiveness every 3-5 years.

- That the USDRE initiate appropriate action to improve industry's visibility of laboratory activities.

- That the DoD undertake the initiation of a formal process to develop operational concept projections to provide scenarios of future military operations. This document should unify the various Service perceptions, and then be used by the laboratory community to guide their respective technology developments.

- That the USDRE undertake a new approach to coupling the laboratories with the Operational Forces by providing the Unified and Specified Commands and subordinate component commands with modestly sized technical staffs, drawn from the DoD laboratories.

- That the USDRE task each military department to establish a formal "Logistics R&D Program." It is perceived that this area of R&D consistently receives inadequate attention by the Services.

- That the USDRE support the expansion of critical demonstration programs by providing the ASD(RT) with a $300-400M set-aside.

- That the USDRE support the establishment of a Defense Center for Research in Simulation Techniques and Technologies.

- That the USDRE form a special task group to examine the optimum mechanism for establishing a new Center for Micro-electronics and Computer Sciences.

- That the USDRE support the expansion of the Joint Electronic Warfare Center (JEWC) in San Antonio, TX, to strengthen the DoD capability to develop and apply new electronic warfare techniques; to focus on joint and combined technology-operational techniques; and to conduct test and evaluation.

- That the USDRE support the establishment of a formal Command and Control Research Program and Center, which is consistent with the DSB report of 1978 on C^3 acquisition.

Further amplification of each of the above recommendations is included in the report.

57-279 O - 87 - 40

Section 1
INTRODUCTION

On 3 September 1981, Dr. Richard DeLauer, under Secretary of Defense for Research and Engineering, established a review of Department of Defense laboratories. This review was undertaken by Dr. Robert Hermann under the direction of Dr. Robert Cooper with the assistance of representatives of the Army, Navy, Air Force and DARPA.

During the course of the review, 28 laboratories, R/D centers, and related organizations were visited; a host of industry and government officials were interviewed; and four major industrial associations (ADPA, AIA, EIA, NSIA) were consulted (see Appendix, pages 4, 5, and 7). In addition, an industrial advisory group was formed, in part from the 1981 DSB Task Force on the DoD Technology Base, to advise, critique, and comment on the final report and its development.

Section 2
BACKGROUND

The "DoD Laboratories" are a set of 73 laboratories, research and development centers, research institutes and development boards which include 60,000 people, $6 billion in capital facilities and equipment, and 1981 expenditures of more than $5 billion for research and development effort.

An anxiety exists in the minds of many who observe, work with, and work in the laboratories and R/D centers about the health and future of these activities. They are concerned with a variety of issues and trends which seem to dominate the present circumstances:

- Many laboratories have had consistent difficulty in recruiting new, young engineers at the GS-5/7 levels, and also in retaining the most competent and experienced scientists and engineers. The salary constraints of government employment, escalating industry salaries, increasing bureaucratic administrative burdens in the laboratories, and other factors are causing a loss of work force competence.

- The procurement policies, procedures, and practices forced on the laboratories by legislation and regulation cause an excessive investment in non-productive activities and are so burdensome and counter-productive that innovation is greatly constrained.

- The facilities and, in many cases, the lab equipment are outdated, inefficient, and in need of replacement.

- The laboratories seem to be working on the wrong problem from either viewpoint of technology opportunities or operational needs. Also their ability to adjust and respond to new technology developments seems unduly slow.

- It is evident to all observers that the process of technology transition to operational forces is not working well and some (but surely not most) of the blame is levied on the laboratories.

- The relationship between the DoD and our universities could be measurably improved to the advantage of both sectors.

These concerns have stimulated several previous laboratory reviews which have resulted in relatively consistent conclusions and recommendations:

- The laboratories are essential.
- They need to be better.
- Their personnel practices must be upgraded.
- Their procurement practices must be streamlined.
- Their facilities and equipment need to be kept up to date.
- Their relationships with universities should be improved.

Many of these recommendations have been acted upon with varying degrees of completeness but there is broad agreement that more needs to be done to correct the deficiencies in the laboratories and the processes which surround them.

With this background, the present review was initiated.

Section 3
FINDINGS

3.1 THE TECHNOLOGY ENVIRONMENT SURROUNDING THE LABORATORIES HAS CHANGED

The technology environment in which the laboratories find themselves today has substantially changed and their role and mode of operation has changed. It must continue to change with the environment, as must our collective judgment about the roles and limitations of these centers.

Some of the anxiety about the health of the laboratories comes from those who compare today's laboratories with the performance and influence of the labs of past generations. There may be some merit in making such a comparison but for the most part it is not appropriate. The technology environment surrounding the laboratory has changed profoundly in the past two decades. There has been a massive proliferation of new technologies which have relevance to defense. The technologies have infused the civil and commerical sector in an all-pervasive way causing, among other things, great competition for skilled personnel and a substantial reduction in the leverage DoD can use in the high technology market place. Technology options are now wider and the technical questions are more complex; in part because of the increased number of functions being built into systems, and in part because of the phenomenal increase in parts count, cost and development time.

The relative position of the U.S. in technology has changed. In the early years after World War II, the U.S. had

an overwhelming superiority in both the technology and industrial base. Since then, Western Europe and Japan have made remarkable strides and now challenge the U.S position in many areas. Within the U.S., the Defense Department no longer dominates the high technology market as it did in the early 1960's. These factors change many aspects of laboratory life including the type and range of personnel skills needed, the relationship with Program Managers and Commands, and with industry.

3.2 THE NEED FOR AND UTILITY OF THE LABORATORIES AND R/D CENTERS

Most observers and participants in the DoD acquisition process agree that the DoD does need a strong and viable set of R/D laboratories and centers such as those now in existence. There are varying opinions as to which are essential, what the fundamental problems confronting these institutions are, how they should behave, and what corrective measures should be taken. However, there is nearly universal recognition that:

- Good work has been and is being done by the labs through in-house work and sponsored efforts in industry.

- Much of this work has resulted or will result in the transition of new technology into systems now in use in our operational forces.

- Most of the functions assigned to these centers cannot reasonably be transferred to private industry.

3.3 THERE REALLY IS A LABORATORY PROBLEM

These positive assessments are clouded by the concern by many that we may not be getting our moneys worth. For the dollars, personnel, investment, and management attention involved:

- Too little new technology finds its way to the operating forces and, while the laboratories are not the primary agents responsible, they can play an important role in improving this process.

- The government does not seem to be a very smart buyer. Again, the Systems Commands and major Program Managers are primarily responsible but improved laboratories with better procedures for their participation would be a positive factor.

- The quality of laboratory scientific and engineering personnel is eroding.

- Bureaucratic procedures and perhaps an aging work force are suppressing the innovation necessary to advance the technology of these times.

After reviewing past reports, visiting nearly one-third of the laboratories, and listening to the views and recommendations of industrial managers and associations, the judgment clearly emerges that there are several fundamental problems involved with the laboratory performance and the relationship between the laboratories and the ultimate users of their efforts. While the internal situation of the labs should not be judged as disastrous yet, it seems clear that

if the business of the laboratories were to continue to be conducted in the future as it has been in the past 5-10 years, the health and viability of the laboratories and their role in the whole DoD research, development, and acquisition process will be jeopardized.

Many who work in the laboratories agree with the assessment that we are not getting our money's worth. They are profoundly frustrated by the manifold constraints in their personnel system, the procurement procedures, and the programming and budgeting process.

Thus, while the laboratories are essential, it is imperative that changes in the process be made to correct both their real and apparent deficiencies. Either the real deficiencies or those which are perceived could severely damage the system if left unchecked for very long.

Prior studies have also reflected these concerns and, to the extent corrective measures have not been implemented the situation has deteriorated. The urgency is now greater than ever; the problems which caused concern in the past have grown, the technology competition has increased, and our operational posture has become more important.

3.4 THERE IS A DISCONNECT BETWEEN THE LABORATORIES AND THE OPERATING FORCES

Perhaps more serious than the problem of the internal health of the laboratories and R/D centers is the relationship of the acquistion process to the operational forces and the general problem of transitioning the products

of the labs into operating systems which are affordable, reliable, and supportable and fit into realistic operational concepts. This issue is dominated by the broader acquisition management process primarily involving Program Managers which has received very high level attention. Deputy Secretary of Defense Carlucci has originated a set of 32 initiatives aimed at improving the acquisition process. However, the laboratories are also an important element of this process and can be an important instrument in improving the transition of new technology.

We have not effectively applied many of the new and potentially high leverage technologies which have been available over the past two decades. A cursory review of the forces and systems now in the field and being fielded will lead to the judgment that we have been ineffective at both translating technology into a fielded system and adopting operational doctrine and concepts to take advantage of modern technologies and techniques.

We have now suffered many years of the consequences of fielding complex modern systems based on high technology and design rules driven by technical performance. There has been a systematic disregard of issues such as:

- Whether we can afford to buy enough of the item to gain the operational leverage which formed the basis for the investment.

- Whether the system will be reliable enough to be available when needed while avoiding unusual maintenance cost and impact.

- Can the system be maintained by the anticipated maintenance work force without unreasonable cost or impact on the operational availability of the system.

- Will the logistics concepts, procedures, and personnel be adequate to maintain the system's operational availability.

The program managers and supporting laboratories need to make some changes in approach to reverse this situation.

The laboratories have great difficulty understanding and representing what will be needed by operational forces. Industry observes this as an annoying lack of coherence and direction on the part of the government which creates inefficiency through lack of consistency. Laboratory personnel themselves are frustrated at not being able to decipher what operational authorities need through what is displayed or expressed to the labs. The operational commands need a better relationship with both the labs and the system commands.

Functions which are integrated with and imbedded in the command structure such as communications, command and control, electronic warfare, and the battlefield application of intelligence have suffered through lack of adequate means of technology application. These functions demand not only the ability to rapidly adapt to new technology but also the need for combined operational-technical competence in integrating these new technologies into operational doctrine and concepts. The laboratories are organized along the lines of engineering functions, platforms, or commodities and are not well equipped to address these problems.

3.5 EVERYONE FEELS CHEATED BY THE PROCESS

In general, all participants feel cheated by the process through which the laboratories must make their contribution. Industry is convinced that it could do so much more for the defense effort if the laboratories (as well as others) could consistently represent operational needs and could use reasonable procurement procedures in acquiring their goods and services. They also resent what they feel is unfair competition by the laboratories from a privileged position. Laboratory personnel are frustrated by a nearly unbelievable set of personnel procedures, administrative burdens, and excessive procurement process constraints. Examples abound such as budgetary instability and several levels of reviews, audits, and inspections. They are further troubled by the inability to obtain consistent direction about real operational needs and resource levels. They object to what they see as overly conservative system Program Managers who are unwilling to use their technology products. The Program Managers are unhappy with the lack of realism, insensitivity to cost, and schedule demands on them displayed by their laboratory counterparts. The record of major system cost and schedule overruns provides some justification for this attitude. The operational commands are disappointed and cynical about the application of new technology to their problems as a result of years of observing that it takes an inordinate amount of time to get new technology into fielded systems, and when fielded they are often unreliable, hard to maintain, and difficult to support. Finally, informed citizens feel cheated by the lack of both efficiency and effectiveness of this application of their substantial tax dollars which reflects into the political active assessment of "waste in the DoD."

Those responsible for managing the acquisition process both in the executive branch and in congress must take steps to correct this destructive and seemingly pervasive attitude. It is an injustice to the nation and to those whose talent and energy are applied to the problem of national defense.

3.6 THE TIME IS RIPE FOR IMPROVING DoD LABORATORY AND UNIVERSITY RELATIONSHIPS

The university and DoD laboratory relationship has waxed and waned over the past 30 years with perhaps the worst of times being represented by the late sixties and early seventies. The relationship was obviously strained because of reaction to the Vietnam War, but also because a decreasing amount of DoD funding was going to the academic community.

Since the mid-seventies the situation has improved, with DoD and the university community acting in concert once again. Funding for university research has not reached the levels of the early seventies, but the relationship or cooperation for the mutual benefit of universities and the DoD is improving.

However, the nation now faces a severe shortage of technically trained people. This is reflected in the lack of graduates for government and industry, university faculty, graduate students, and in the lack of facilities to do outstanding research. Both the DoD and the universities should have a high motivation to jointly help to solve their somewhat separate problems. Much of the apathy and antipathy of the past decade is past and both the need and opportunity to solve some of these problems together seems to exist.

This problem is being addressed by several study groups on a nation wide basis. In particular, the Defense Science Board (DSB) has just issued a report entitled "University Responsiveness to National Security Requirements."

3.7 THERE ARE NEW TECHNOLOGIES AND TECHNOLOGY BASED OPERATIONAL FUNCTIONS WHICH NEED SPECIAL ATTENTION

As new technologies have emerged with increasing rapidity, the existing lab structure and work force have not been able to keep up with and organize to apply them to defense problems. Further, the gradual infusion of new technologies into U.S., allied, and opposing forces has created new operational situations and opportunities which require a combination of operational and technical competences to exploit. There are a few specific areas of new technology opportunities which require extraordinary management attention. Those recommended for specific attention now are:

- Micro-electronics
- Software Research and Development
- Artificial/Machine Intelligence
- Electronic Warfare
- Command and Control

Each is treated in more detail in the section covering recommended actions.

Section 4
RECOMMENDATIONS

To help correct some of the deficiencies noted above, and to respond to the technical and operational challenges which face the Department of Defense, several actions are recommended. These initiatives are listed below, and outlined in more detail in the following pages.

1. Upgrade Personnel Practices
2. Streamline Procurement Practices
3. Modestly Increase the Rate of Modernization of Facilities and Equipment
4. Improve University Relationships
5. Establish External Advisory Groups for the Laboratories
6. Establish an Effectiveness Review Process for the Laboratories
7. Improve Industrial Visibility of Laboratory Activities
8. Develop an Operational Concept Basis for Guiding Technology Development
9. Expand Laboratory Relationships with Operational Forces
10. Strengthen Service Logistics R/D Programs
11. Expand Critical Technology Demonstrations
12. Establish a Defense Center for Research in Simulation
13. Establish a New Center for Micro-electronics and Computer Science
14. Form an Electronic Warfare Techniques Development Center
15. Establish a Formal Command and Control Research Program and Center

It is difficult to order these initiatives in a single, declining order of importance. However, they can be grouped as follows:

- The first seven topics are aimed primarily at the internal health of the laboratory system as an operating technical organization and its relationship to industry.

- The second four topics are aimed at the relationship of the laboratories to operational forces and the technology transition process.

- The final four topics address possible initiatives in new technical/operational disciplines.

The above initiatives can be evaluated and prioritized against several criteria.

The greatest return on management energy invested will result from improving our ability to transition technology into operational capability. Thus, improving the lab/operating command connection, generating an operational projection for technology management, an increased technology demonstration program, and logistics research and development investments have high leverage. However, several other actions aimed at other primary objectives will help in this respect also. For example; an improved simulation capability and closer relationship to training operational commands could markedly improve the relevance of lab activities;

inclusion of command representatives in the technical review process will help; and the initiatives in EW, C^3, and Logistics will generate useful mechanisms for transition of technology.

It is also true that without sustained quality and competence in the laboratories, a better connection to the Systems Commands and Program Managers will not be of much value. Therefore, improving the personnel practices of the laboratory process is absolutely essential. Of lesser but still profound importance are the issues of: a quality review process, procurement practices, facilities, and general purpose equipment.

Finally, the need to generate new energy and innovation in the technical areas of micro-electronics and computer science, simulation, logistics, electronic warfare and command and control cannot truly be evaluated as secondary. They are needed because of the essential nature of these disciplines and the dependence of our defense posture on our ability to translate their leverage to our operational forces. They are also needed to demonstrate to ourselves as well as others that we have the capacity to change and adapt our institutions and our programs to new situations.

4.1 UPGRADE PERSONNEL PRACTICES

An absolute prerequisite for the maintenance of effective laboratories is a competent work force. The personnel practices of the past 5-10 years have caused an

extensive erosion in the competence, morale, and effectiveness of this work force and, if continued, would lead to the decline of the laboratory system.

Some very important changes have already been initiated with congressional action to raise the pay cap and relax the limitation on high grades. These will provide some much-needed flexibility to laboratory managers to promote good young engineers who have waited at lower grades while reductions in numbers and high grade constraints have held them back.

However, more is required. There are other opportunities to help create and maintain a qualified, motivated, and professional work force. Many of the recommended actions outlined here are already started and only need further support and emphasis. The laboratories need to be encouraged and the procedures need to be made easier for the labs to exercise many of these opportunities.

Recommended actions include:

4.1.1 Expand NWC/NOSC Demonstration

- The NWC/NOSC personnel demonstration should be extended to other centers. Under new guidelines, both NWC and NOSC have created excellent personnel programs which reduce the paperwork of administration and greatly emphasize performance as a basis of promotion, competition, and priority under reduction-in-force procedures. These programs are well thought out and working well.

Other laboratories should be directed to submit proposals within the guidelines which governed the NWC/NOSC demonstration and are tailored to the particular geographic, service and skill needs of each laboratory.

4.1.2 Resurrect PL-313-Like Positions

- Resurrect a modest number of PL-313-like positions. During the 60's and 70's the PL-313 position was a powerful tool for quickly and efficiently acquiring the services of specially qualified scientific and engineering skills on behalf of the government. Yet, it was not a very large population. Although a flexible salary level was one of the leverages available under PL-313, the flexibility most important to resurrect is the ability to designate the skill and the person needed and acquire his/her services rapidly. This flexibility is still needed, is not available through the SES process, and should be created.

4.1.3 Reduce Administrative Impact of Civil Service Reform Act

- Reduce some of the administrative burden and excessively bureaucratic procedures introduced by the implementation of the Civil Service Reform Act of 1978. While the motivation for this act was correctly aimed at efficiency and professional performance, and many of its features are

worthwhile, it also produced some glaring new unproductive burdens which should be corrected. For example;

- Senior Executive Service positions are now routinely left open from 12-24 months because of the extensive and lengthy process of filling an open position. Along with the many other difficulties of laboratory leadership, delays of this magnitude are truly damaging. The harsh effects are amplified even more during these times when inequitable pay is causing alarming departures of competent leaders.

- Fix the merit pay system! During visits to the laboratories, no other subject gave rise to such intense and emotional criticism as the Merit Pay System. The laboratory management and the work force felt doubly cheated by the 1981 merit pay exercise. They all dedicated an unreasonable investment of the time and talent of their organizations to fulfill the excessive paperwork burden of its administration (one organization estimated that it cost $5 of effort for every dollar awarded). Then, at the last minute, the government reversed itself and made no distinction in pay on the results. This demonstrated a gross insensitivity by wasting a lot of effort and hypocritically disavowed the underlying objective of the program.

4.1.4 Work on a Differential Pay System

A differential pay system for selected scientific and engineering personnel is needed. The concept of comparable compensation is essential for the health of the government in general, and in the case of selected scientific and engineering skills (at this in history,) it is crucial. Our laboratories, which we agree are essential and must be competent to perform their function, cannot compete with industry in some important aspects under present practices. Most importantly, they cannot compete for B.S. graduates in engineering, computer science, and some specific scientific fields. The salary structures of industry and government may differ by a minimum of $4,000 and routinely as much as $10,000 per year at these low-experience levels. Although some differentiation is already made for engineers through higher entry-level grades, it is totally inadequate and some form of special compensation must be developed.

The second crucial area of competition is at the senior technical manager level. Most of these laboratories and centers involve guiding several hundred to several thousand personnel and several hundred millions to billions of dollars of effort. To expect that the government can acquire and retain the level of professional technical management capability necessary to guide these efforts without special compensation is unrealistic. At least a few positions in each laboratory, R/D center, or major technical activity should be designated for special salary provisions. This would not be expensive (for example 300 positions with an average of $10,000 per year differential would total 3 million/year). It would demonstrate that the government

valued what it was asking these centers to accomplish and the advantages would be amplified manyfold by improved motivation and morale of the 60,000 to 100,000 person work force.

4.1.5 Laboratory and Technical Directors Should Have Tenure

Laboratory Directors and Technical Directors should have substantial tenure positions. It would be desirable that they stay at least 3 years. Corporate memory is a problem for the laboratories and is one of the most criticized aspects of laboratory management by industry.

4.1.6 Expand Student Support Programs

There are also several important actions involving improved educational opportunities which sould be undertaken to help recruiting and retention, improve the competence of the work force, and foster a quality professional environment. No one action is critical but the collective emphasis on the recruiting, retention and improvement of quality personnel is crucial:

- Student utilization programs should be expanded. Co-op programs have proved to be excellent for recruiting high quality young engineers. These programs should be expanded. Where possible, hiring graduate students on a part-time basis should also be increased.

- The Services should increase their use of the ROTC program to acquire scientific and engineering officers.

- Post baccalaureate graduate fellowships for defense science and engineering employees should be expanded, again with a suitable post education commitment.

- There are a few areas of specialization in which the DoD needs call for targeted post-graduate education with the post education work commitment in industry. The Air Force and Army already have such programs in cooperation with industry for thermionic tubes, aero-propulsion vertical lift technology, and other areas. This is a useful approach and expansion should be encouraged.

- A new initiative recommended is that the Services and Defense Agencies should also establish an auxiliary "Defense Engineering Training Program" patterned after the ROTC program. The last two years of college should be supported with a two-year post-education commitment in a civilian defense engineering job. Summer employment opportunities should also be included in this program.

4.1.7 Provide Consistent DoD Policy

Finally, nothing will do so much for the work force and its management as responsible OSD and Service management. If the lab directors and work force had confidence that senior DoD leadership had a clear direction and objectives and that this leadership were prepared to stand firmly for

programs and actions which placed highest values on the primary purpose of creating a Defense capability, it would do wonders.

4.2 STREAMLINE PROCUREMENT PRACTICES

The present practices by which laboratories and R/D centers presently procure material, computers, and services cannot be rationalized. They create massive, unproductive efforts. They cause unnecessary and extensive delays which produce deficiencies in capability, which are usually not recognized or quantified by those enforcing the procurement practices. They violate the good sense of all participants. They cause extensive waste in the industrial sector. No one will defend them as they are.

These judgements are true for the whole acquisition process of the DoD (which is generally better than the rest of the federal government) and thus the laboratories cannot be expected to be extricated completely. However, there are some steps which would substantially reduce the burdens and delays on a large group of small R/D procurements, which constitute a very large percentage of the actions undertaken by the laboratories.

4.2.1 Improve Procedures for Small Contracts (Less Than 500K)

This review was not extensive enough to do a complete job of defining all of the steps needed to improve the procurement process. It is a vast labyrinth of laws and regulations which are intertwined with a language which tends

to keep all but lawyers and contract administration specialists intimidated. However, there are some initiatives which can be reasonably identified.

- The "Determination and Findings" threshold should be raised. Congress has now authorized this to be raised from 100K to 5 million. The Services should assure that the majority of this flexibility is delegated down to the laboratory and R/D center director.

- Special fast-track contracting procedures should be streamlined further for R/D procurements under 500K. Congress has already assisted in this by raising the level above which pre-contract certification is required to 500K.

4.2.2 Relax Technolgy Base Obligation Constraints

Obligation and expenditure constraints should be relaxed for technology-based efforts. The pressures to assure a complete expenditure profile has placed extraordinary constraints on the contracting processes of the laboratories. While this pressure may have a rational basis over the whole investment account, it is inappropriate for the relatively small and numerous contracts of the technology base effort.

4.2.3 Select Study Group to Review Small Procurements

These recommendations, even if completely implemented, are not intended to be complete and they are not

enough. The constraints of the contracting process have gotten out of control and it is recommended that a special team of contract administration specialists be identified to specifically address what can be done to improve the situation for small R/D contracts.

4.3 MODESTLY INCREASE THE RATE OF MODERNIZATION OF FACILITIES AND EQUIPMENT

The laboratories appear to be somewhat more deficient in modernization than the rest of the defense establishment, and less well represented in the resource allocation process. While the life or death of the lab system does not ride on this issue, the labs should be allocated a larger share of the available money for facilities and equipment.

4.3.1 Support LMTF Recommendation on Facilities

Many of the facilities are substandard, inadequate, obsolete, or energy inefficient, and they need to be updated. Also, advancing technology in new programs will require appropriate facilities and new facilities need to be provided to the laboratory community. The Laboratory Management Task Force under USDRE recommended that significant monetary investment in R&D facilities for each Service should be insured over the next 10 years. They sought to have the DoD establish a laboratory facilities modernization policy such that replacement could take place in a timely manner and could be tailored to the characteristics of the laboratory systems in each Service. About $70 million each year for each service over the next 10 years would be required. This recommendation is supported.

4.3.2 Support LMTF Recommendation on Equipment

The general purpose equipment posture of the laboratories is similar. The Laboratory Management Task Force recommended that the DoD modify existing regulations (in this particular case, DoD Directive 7410.4) to permit depreciation charges at appropriate laboratories. Also, they suggest that DoD establish a laboratory equipment modernization policy to insure that general purpose equipment is replaced or acquired in a timely manner. To accomplish this, the Laboratory Management Task Force suggested that each Service have an equipment modernization program of at least $25 million to $30 million each year for the next 10 years. This recommendation is also supported. These facility and equipment modernization programs are necessary if the DoD Laboratory system is to remain competitive in high technology area.

4.4 IMPROVE THE DoD/UNIVERSITY RELATIONSHIPS

A series of actions are recommended to support the goal of improving the DoD University connection;

4.4.1 Support DSB Recommendations to Increase University Support by Defense with Associated Equipment Modernization

This recommendation has been put in place by putting $30 M into the FY83 budget ($10 M per service for the next 5 years for a total of $150 M). This should be dealt with by the Services under the cognizance of DoD to insure that the university equipment is well utilized and that the

program does not become a source of funds for things like oscilloscopes and equipment that could well be purchased by the university. These should be items that are of high interest which provide quality facilities for universities to do DoD research. This equipment needs to be funded within the university community, in part because in years of declining budgets within DoD, the DoD support for university facilities was lacking. This was true in the laboratories as well and is discussed in Section 4.3.

4.4.2 Support DSB Recommendation to Establish New S&E Fellowships

The DSB recommended the establishment of new scientific and engineering fellowships in the universities. The DSB recommendation included a $15,000 stipend to the student during the time that he is involved in the university education process. The fellowships will help get post-graduate education on its feet and will help the universities develop a faculty and develop areas of expertise such that it will be possible for the university community to be preeminent in science.

4.4.3 Continue the Dialogue Regarding the Security of Intellectual Property

The issue of secrecy regarding scientific and technical information relevant to the creation of military capability is a potentially divisive issue between the DoD and the academic sector. The problem is a broad one and extends well beyond the laboratory interface with universities. It is of critical importance to this interface,

however, and it is imperative that a dialogue continue between all parties in pursuit of a rational solution.

4.4.4 Expand Student Utilization Programs

The student utilization programs should be expanded. Co-op students are good sources of new people for the laboratory community. Once people are involved in the laboratory in the summer co-op programs, they generally will at least consider the laboratories favorably when looking for a job after graduation. Along the same lines, graduate student hiring should expand. In this case, the university graduate students can work part time in the DoD laboratory, obviously if it is close to the university.

Another area of student utilization programs is research assistanceships. The Air Force and the Army both offer research assistanceships which are essentially fellowships whereby the student is given a stipend but he does not have to spend any time in the Service or in the Civil Service. These assistanceships are in areas of critical need for the Service. The Army has programs in helicopter aerodynamics and helicopter design, the Air Force has programs in thermionic engineering, composites and propulsion. These programs are designed to build up the technical expertise of the country so that the DoD will have access to such expertise and that there will be people who can be called on as consultants from private industry to work on difficult or time critical problems.

4.4.5 Establish a Two Year Undergraduate Program for Civilian Employment Patterned after the ROTC

In addition to the DSB suggested increase in the ROTC programs, a two-year undergraduate program should be established for the last two years of college, providing an engineering degree while requiring DoD employment for two years afterwards. This would essentially provide the same benefits as the ROTC program, except it would appeal to those who are not sure they want to serve two years in the military, but would like to serve two years in a Defense position. This may provide a different kind of incentive to university people in their junior and senior year which might also entice them to stay on with a DoD technical activity. This seems like a particularly good idea at the lower experience levels where the Services need to recruit quality people, but have problems in that industry is offering much higher salaries than the DoD can offer.

4.4.6 Increase DoD and University Emphasis on Industrial Education Related to Logistics and Manufacturing

Some of the DoD deficiencies in our logistics and manufacturing techniques are derived from the more general national problem of lack of emphasis and shortage of skilled personnel in this area. The DoD and universities should work together to enhance the prestige of these critical professions, enhance the curricula in the universities, and increase the number of students being trained.

4.4.7 Establish Defense Centers of Excellence with Universities in New Technology Areas

There should be Defense centers established with universities in new technology areas. These new technology

areas would include simulation, micro-electronics, artificial intelligence and software research and automation. These new technology areas are ripe for starting new curricula in universities. They would be multidiscipline in nature and cross departmental. However, there must be a mutual need to establish a center of expertise with university help and university participation. This idea seemed to work well where the Army's Corps of Engineers' Construction Engineering Research Laboratory is co-located with the University of Illinois and the Cold Regions Research and Engineering Laboratory is at Dartmouth College. Both of these have a benefit for the university and the Service. Laboratory people co-located can use the same facilities and provide an interchange between the day-to-day practical problems of the Defense Department with the perhaps more theoretical aspects of the university and the faculty research programs. Expanding into new areas provides a good method for increasing the involvement of universities in DoD research and development, but it does it in a way that involves the faculty, the students and the DoD researchers as a team.

4.5 ESTABLISH EXTERNAL ADVISORY GROUPS FOR EACH LABORATORY

The Services and Service labs should be encouraged to establish external advisory groups drawn from industry, universities, and operational command representatives. Although the interaction with such groups brings with it a substantial investment of time and energy and there can be a conflict of interest issues. They can:

- Bring external competence to the problems of the laboratories;

- Be a source of new ideas and perspective;
- Provide a valuable component of corporate memory for a laboratory, and;
- Assist in providing visibility to lab activities for industry and academia.

The value of these contributions can be great and well worth the investment. It would be natural for these to be formed under each service science advisory board and to participate in the effectiveness review recommended elsewhere in this report.

4.6 ESTABLISH AN EFFECTIVENESS REVIEW PROCESS FOR THE LABORATORIES

A number of benefits would result from the creation of process for external expert review of the laboratories and R/D Centers every 3-5 years.

The basic objectives of this initiative are:

- To provide a routine and credible means of assessing the health of each laboratory and research, development and acquisition process in which that laboratory is imbedded;
- To provide an additional mechanism for visibility of the DoD R/D activities by industry, the universities, and operational military representatives, and;

- To provide a channel for the display of in-house direction and work to nationally recognized experts.

The USDRE should task the Defense Science Board to establish a permanent panel to develop the criteria to be applied, define the process of review, and monitor the implementation. The Military Departmental Scientific Advisory bodies should be the primary means used to review Service laboratories and DSB should take the lead for any other laboratory or technical activities to be covered by this process. In order to prevent unnecessary duplication, the individual advisory bodies for each laboratory, recommended elsewhere in this report, should be employed.

4.7 IMPROVE INDUSTRIAL VISIBILITY OF LABORATORY ACTIVITIES

One of the major complaints of industry is that the laboratories too often compete with industries in areas where industry can perform. They further feel that this competition comes from a privileged position in terms of decisive influence and access to information. They note that industry provides detailed reviews of their independent research and development; whereas, the labatories rarely provide such a view to industry.

In many aspects there is no way to avoid the special decision role which the labs must play and their privileged access to government intentions and information is necessary. Nevertheless, these complaints have a major element of truth behind them. Even though they are often

57-279 O - 87 - 41

extrapolations of isolated experiences, actions can and should be taken to reduce the sometimes unnecessarily adversarial nature of lab-industry interactions.

- A principle initiative should be an annual publication by each DoD laboratory describing its in-house R/D activities as a counterpart to industry's R&D technical plans. There are limitations to this symmetry, of course, since the government must control access to sensitive information. Thus, the laboratory publications can only go as far as practical at the unclassified level.

- Industry participation in laboratory advisory groups and evaluation reviews will also provide some improved accountability of government interactions and activities.

- Industry participation in the development of the operational concept projection recommended elsewhere in this report will be helpful as well.

4.8 DEVELOP A FORMAL PROCESS FOR AN OPERATIONAL CONCEPT PROJECTION AND APPLICATION

In order to sensibly evaluate and prioritize DoD efforts to create and apply technology to the problems of national defense, it follows that we must have some notion of the nature of the military operations to which these applications might be applied. The Defense Science Board Summer

Study panel on technology base found this logic appropriate in the methodology they used to identify technologies with potential for "order-of-magnitude" changes. Under the term "Scenario projection," they developed a brief description of some of the most relevant features of how military operations might be conducted in the 1990's in order to assist in the prioritization of new technology opportunities. The Department of Defense should now undertake to develop and maintain a more complete and rigorous document which would project technology opportunities and likely future military operational concepts in a form which would be useful in guiding technology development and application.

The existing procedures for developing and stating required operational capabilities are both essential and useful, but also inadequate to project the nature of military operations ten and twenty years into the future in language useful for making technology management decisions. Yet, that is the time of operational maturity for the weapons and systems which will be generated through application of technology choices of today. The operating commands are not properly staffed to assess and project the combination of technology opportunities and operational procedures which together are likely to form the operational concepts of the future. The laboratories are not charged with this responsibility and find it difficult to participate in the operational requirements process. Present Service staffs attempt through various techniques to make this projection and do so with some success. However, where new concepts might cross Service (or Allied) boundaries, or cause a substantial change in roles, missions, or doctrine, these techniques are severely limited and have not proven to be adequate.

There also exists a widespread conviction that the overall DoD capability to plan, project, and strategize with consistency is not adequate. This, of course, makes it more difficult for subordinate functions such as technology managers to do consistent planning within a larger effort. This initiative is not recommended as a means of solving the broad Defense planning and projection problem. Rather, within the vagaries that will always exist to some extent in our top-level planning, this projection of likely operational concepts is intended to assist in forcing technology choices to be focused on a value system of operational utility.

The Secretary of Defense should task the Defense Science Board to supervise the preparation of this projection and to update it every two years. The DSB is an appropriate body because it is the premier advisory body to the Secretary of Defense and has within its membership nationally recognized leaders in scientific, industrial, and military thinking and can mix that membership with active government, military and civilian leaders. This mixture of separate professions and competencies has been, over the years, a dominant force in influencing (in many ways) how our defense establishment is structured. It is important to capture their judgment in an orderly manner for the purpose of building a consensus strategy to create and apply new technology.

Finally, a small, permanent supporting staff should be organized as the secetariat for this effort. It should be contained within the new Center for Strategic Concepts Development now being organized at the National Defense University to increase their emphasis on the military operational arts. Assignment of this responsibility should provide some useful synergism and complementary emphasis.

The "Operational Concepts Projection for Technology Management" should be submitted to the Secretary of Defense by the DSB after it has been reviewed and commented on by the Joint Chiefs of Staff, Unified and Specified Commands, the Military Services, appropriate Defense Agencies, and OSD Staff elements.

4.9 EXPAND LABORATORY RELATIONSHIPS WITH OPERATIONAL FORCES

One of the most common criticisms of the laboratories is the apparent lack of coupling between what the laboratories are doing and sponsoring and the needs of operational commands. This judgement is reflected in many forms:

- Those who have the opportunity to observe our forces often note that these forces are not modern in many ways and that very reasonable application of newer technology could have great leverage. They conclude, therefore, that the transition process is not working well.

- There has been an increasing awareness that some of the sources of major weakness in our operational forces is lack of reliability, maintainability, and supportability of equipments being provided. Nevertheless, the primary drive from the laboratories and the program managers often seems to be the application of new science and new technology to improved technical performance without emphasis on manufacturing and logistics.

- Many of the more contemporary advances in military force capability involve the application of technology and highly technical systems skills to the force management problem(C^3), to the application of signals in military operations (EW), and to the application of intelligence and sensor products to support platform and unit maneuver and weapons control.

Most laboratories are organized around an engineering function, a military platform, or a producible commodity and are not as capable of dealing with the whole and the connecting networks involved in grouping these all together with men and procedures into a command organization to create a force.

- There are great opportunities to apply available technology and competent technical judgment to the systems and forces now in the field with great leverage. However, we are organized primarily to bring new technology into the field through the developments of new systems, not the application of new technology to existing systems. Product improvement of fielded forces could be enhanced significantly if we recognized that product improvement and logistics support are truly sophisticated technical functions, worthy of our finest and most innovative people. Both organizationally, and culturally, we need to recognize and foster these useful applications of technology in support of military forces for there are great

opportunities available. These opportunities can often be less expensive, more quickly implemented, and more rapidly integrated into the operational, maintenance, training, and support environment of the forces.

The objectives of this initiative are:

- To improve the laboratory awareness and understanding of the operational concepts which their scientific and engineering efforts are supporting;

- To illuminate the reliability, maintainability and supportability issues for both the laboratories and the commands they ultimately support;

- Provide an improved channel for laboratory and command cooperation in fielded product improvement, and;

- Provide an improved mechanism for the evolutionary application of technology to improve command C^3, EW, and intelligence application.

To accomplish this, the unified, specified, and subordinate component commands should be given modestly sized technical staffs, some development funds, and the responsibility for the definition of and, on a limited scale, the acquisition of evolutionary force improvement through field system modifications and improved coupling or netting of assets.

The command technical staffs should be formed from the personnel from the laboratories under personnel administration and career management of the laboratories but operating as an integral part of the commander's staff. The Services should take the responsibility for providing these staffs and the funds for the specified Service component commands perhaps through a designated lead laboratory. USDRE should arrange for Unified Command needs through the Service and Defense Agency laboratories and technical centers.

4.10 STRENGTHEN THE SERVICES LOGISTICS R&D PROGRAMS

One of the most pervasive problems of fielding a modern force with the new technologies available is the logistics tail associated with the new systems that are developed and produced. The underlying issues have a sophisticated technical content but we have inadequate mechanisms to bring to bear the best technical minds to this subject. The logistics and supply organizations of the services are trying to develop better capabilities and techniques but it is slow, in part because of the tendency to view logistics as a less sophisticated and less glamorous career than the design of new systems. Historically the laboratories have been aimed primarily at the application of new technology in the development of new systems with improved technical parameters. Thus, the focus on logistics has been secondary at best.

This review did not reveal any new, well ordered set of actions by OSD to resolve the situation. It would be inappropriate, however, to take no action towards improvement. It is also clear that any decisive action must be taken by the Services because the logistics function is

completely embedded in the Services "organize, equip and train" role.

It might fairly be argued that the issue is not primarily a "laboratory issue" except that the laboratories, as presently constituted, do play an important role in the early phases of development of a new system. It has also been argued that new logistics laboratories are needed by each service. This review did not develop enough data or testimony to recommend either for or against this latter suggestion.

It is recommended, however, that each military department be tasked to establish a formal "Logistics R&D Program" with appropriate program element and program management structure and report back to the Secretary of Defense their plans for the conduct of such a program. These programs should at a minimum cover diagnostic techniques, weapons system logistics analysis, automated documentation, advanced maintenance concepts, and logistics management and control systems.

4.11 EXPAND TECHNOLOGY DEMONSTRATIONS

The tremendous development of new technology in the past 30 years has brought rapid increases in new capabilities for weapon systems, but often accompanied by increases in sophistication and complexity. This is particularly true in electronics, not only in the radar and radio world, but also pervading every major weapon system in the form of chips and sensors. These increases in capability, sophistication and complexity require new ways of doing business for the DoD laboratories, for the industrial community and for the Armed Forces.

Too many problems appear after the engineering development process has been initiated. Problems of technology, reliability, producibility, and useability begin to show up and result in dollar and schedule overruns. Often major changes can be made in a relatively simple manner and at low cost when caught early, sometimes even small changes are difficult and expensive to achieve when made at the end of the cycle.

The transition to full scale engineering devlopment is not only a critical point in the devlopment cycle, but unfortunately, is where disconnects usually occur. It is often at this juncture, that the DoD lab transfers a great deal of in-house activity to industry. It is also at this point that the need to develop a method to best fit the needs and concepts of the operational military plans is most critical.

The demonstration and evaluation of critical technologies in an operationally relevant form can often be a useful means of helping to assess the appropriate mode and the military value of a technological application. However, these demonstrations can be expensive and are often not undertaken by the military Services in favor of other needed and less risky applications of resources.

Senior DoD management has historically disagreed with this priority judgment by the Services and has found it convenient to use DARPA as a primary vehicle for such critical technology demonstrations. While this has produced some salutory results, it has also produced some antagonisms between some elements of the Services and DARPA which have

worked against the end objective of fair evaluation and ultimate transition of the technology in question into operational capabilities.

The objectives of this initiative are:

- To provide a mechanism for evaluating and prioritizing critical technology demonstration efforts;

- To increase the level of Service critical technology programs, and;

- To reduce the sources of conflict between DARPA and the Services.

It is recommended that $300-400 million be set aside by USDRE to be used to support the most worthy proposals for critical technology demonstrations submitted by the Services and Defense Agencies, including DARPA. Operational and Training Commands should also be encouraged to develop proposals for in-the-field demonstrations particularly in support of the C^3 and Electronic Warfare functions.

4.12 ESTABLISH A DEFENSE CENTER FOR SIMULATION RESEARCH AND DEVELOPMENT

Advances in modern computer and display techniques make it possible to develop and perform simulations of military systems and operations with a power and realism heretofore unachievable. This is true at the weapon level; platforms and small units; for large unit exercise and tactics

development; and for large campaign representation and doctrinal development.

The need to simulate these various levels of military activity has also increased because;

- The price of energy and the cost of weapons operations have escalated such that sustained live practice and training is often prohibitively expensive. As a consequence, we have a large percentage of our uniformed service men unpracticed in the use of weapons we paid dearly to acquire and we depend on for our security.

- We need ways to develop military operational experience without engaging in conflict. Too much of our practiced doctrine and concepts, particularly at the theater and tactical level, are dominated by lessons learned in WWII, Korea, Southeast Asia, and Mideast conflicts. All agree that none of these are representative of most future conflicts involving U.S. forces. Strategic force planners long ago learned to depend on analysis, exercise and simulation to define the rules of combat in regimes never experienced by man. Theater and tactical level planners must do the same and an increased capability to simulate will make this possible.

The art and practice of simulation has a strong part in present military sevice practice and is an expanding area of interest and investment. It is, properly, distributed to many different developmental and operational activities in order to tailor the application of simulation

techniques to the needs of the particular training or operational commands. This has, however, fractionated the effort with the resultant lack of focus on generic research, common development, maintaining a repository of information about the state-of-the-art, and, most importantly, the development of a community of skilled professionals in the simulation discipline.

This recommendation proposes the establishment of a center of excellence for the application of simulation techniques to the military arts. The objective is the creation of an institution which would insure the continued development and improvement of our skills, capability and practice of military system and force simulations. There are a variety of organizational options to achieve this objective and this review was not sufficient to advocate any particular course of action. However, some elements of an adequate approach include;

- Close association with one or more universities. The context of a simulation program should be very compatible with the aims and capabilities of several universities. This association should be of value to all parties.

- The creation of a private sector organization (such as or similar to the Applied Physics Laboratory of Johns Hopkins University) as a core work force for the development of long-term, professional quality in simulation techniques.

- The constraint of the center to research, equipment and technique development and acquisition,

and technical support to operational and training activities. This role as an organization designed to develop techniques and promote professional technical expertise should dominate rather than act as a bureaucratic coordination or management role function.

A major issue with this recommendation is whether any new organization should be formed around or even include the existing training equipment activities of the Services. They certainly form a large existing body of competence, albeit limited in scope, from which to grow such an organization with its expanded role. Conversely, one can be concerned that development of this broader role might become subordinate to the on-going needs for fielding equipment already defined. In spite of this latter risk, proceeding from the base of these training equipment establishments is recommended.

An ad hoc group should be formed to develop a more detailed implementation plan to form a Defense Center for Simulation Research and Development located with the Naval Training Equipment Center and the Army Program Manager for Training Devices. The Air Force should also establish a larger presence at Orlando as a part of this action. Some additional resources may be required but for the most part the new thrust should be created through private sector organization preferably with a university association. An opportunity for a mutually attractive association may exist at Orlando with the University of Central Florida.

Executive responsibility for the center, which should be defense - wide in scope, should be given to the

Commander NTEC who would respond for these new responsibilities to policies and with resources provided through an executive council of service and agency representatives, chaired by a senior OSD official.

4.13 ESTABLISH A NEW CENTER FOR MICRO-ELECTRONICS AND COMPUTER SCIENCE

The remarkable advances in micro-electronics devices, new sensors, large computers and display systems have created profound new technology opportunities in defense systems. The proliferation of breakthroughs in these areas apply to almost all aspects of military systems acquisition, integration, and operations. It would be fair to say that the maintenance of an effective U.S. military force in the future depends, in large part, on the competence we develop and the judgment we use in the application of these technologies to our Defense and National Security Systems. However, the competence and dynamism of the existing defense institutions and their relationships with industry are clearly inadequate to address the problem with the urgency required. The need to develop this competence and the institutional mechanisms to translate these technologies into operational systems and practice is so overriding that additional extraordinary management initiatives are appropriate.

There is an awareness of the pervasive impact of these phenomena throughout the whole defense community including the existing laboratories and R&D centers. It is not for lack of conviction that the Defense technical community is inadequate in this area. However;

- The government personnel system cannot compete with the private sector for the new skills needed;

- The governmental process for capitalizing new industrial capabilities through its military construction and general purpose equipment programs is far too slow to respond to this rapidly changing area;

- Many of the high-leverage applications address the integration of separate systems to form operational forces. Our collective ability to manage the injection of new technologies into these integration functions such as command and control, electronic warfare, and application of sensor products is extremely difficult, and;

- This proliferation of breakthroughs in the new micro-electronic phenomenology and devices has not been accompanied by parallel breakthroughs in our ability to develop, test, and maintain the necessary software. The need for automated and fault-tolerant design techniques and efficient testing of micro-electrical systems is recognized by both the government and the private sector, but both feel very much behind in their ability to support the software aspects of the problem.

The objectives of forming a new center for micro-electronics and computer science are:

- To create an institution capable of acquiring and retaining the requisite personnel and facilities needed to create and sponsor the creation of new technologies and techniques for Defense needs in the areas of;

  - very high speed and density devices,
  - artificial/machine intelligence,
  - signal processing,
  - software development and automated design and test,
  - new generation Defense oriented computation systems,
  - and to assist in the application of these technologies and techniques into operational systems and practices.

There are a great variety of organizational alternatives by which these objectives might be met. During the course of this review several were briefly evaluated including:

- Expand the role of a single existing service laboratory under a Service executive agent arrangement (an example would be the Army's Electronic Technology and Devices Laboratory at Fort Monmouth, New Jersey);

- Expand the role of one center in each Service;

- Expand the role of one or more non-government center such as SANDIA, APL, or Lincoln Labs, and;

- Create a new institution with a variety of optional forms;

  - primarily government manning capitalization,
  - primarily non-government,
  - primarily university: one or many,
  - various mixtures of government, non-government, and university.

A new institution formed primarily of non-government personnel is recommended. This will provide the best environment for recruiting and retaining the personnel skills necessary to create a center of excellence in these fiercely competitive areas. The creation of a new, defense-wide center in this field along with existing Service and agency laboratories will require careful delineation of responsibilities. However, this should be quite practicable. The area is worthy of increased effort and the Services need their own institutions to aggressively translate these new technologies into the forces.

This study could not give the time and talent necessary to define a specific organizational approach for this new center. It is recommended that the USDRE should establish a separate ad hoc group with membership especially competent in this field to develop the detailed plans, directives, and perhaps legislation needed to proceed.

4.14 FORM AN ELECTRONIC WARFARE TECHNIQUES DEVELOPMENT CENTER

Advances in technologies such as propulsion, materials, micro-electronics, communications, and information

handling have created new weapons and supporting systems which have profoundly affected the nature of modern military operations. Munitions are more lethal and delivery systems can deliver them farther, faster and more accurately. This requires, and technology permits, more precise target acquisition at greater distances, and the control of both weapons and sensors at a distance. All of these trends have caused a fundamental dependence of modern military weapons and forces on electronic and signaling techniques.

Under the functions labeled "Electronic Warfare," "Signal Warfare," "C^3 Countermeasures," "Radio Electronic Combat" and/or "Electronic Combat," modern military establishments are developing capabilities to maneuver in this new regime of military operations. For the U.S. and its allies, the processes for specifying and acquiring the hardware needed is most advanced, but their ability to integrate this hardware into effective operational capabilities is not as well developed. The Soviet Union, however, has placed much greater emphasis on the operational concepts and institutional structures necessary to achieve this integration under their "radio electronic combat" functions and organizations.

The objective of this initiative is to strengthen the DoD capability to develop and apply new electronic warfare techniques. To do so it is proposed that a strong systems engineering capability be added to the Joint Electronic Warfare Center in San Antonio to complement existing science laboratory efforts. At present, the JEWC consists of approximately 140 personnel who are primarily non-technical with strong intelligence or operational backgrounds. In order to develop the new techniques appropriate for modern forces in future operations, it is necessary to include both

the potential of advanced technology as well as operational concepts and doctrine.

By making a substantial addition to the ability of the JEWC to address both the technology and operational aspects of electronic warfare, it can markedly improve its ability to develop such products as:

- Joint EW procedures and techniques,
- Analysis evaluations of alternative EW methods and techniques,
- EW simulation capabilities and results,
- EW test and evaluation proposals and evaluations,
- Technical support to operational and training commands, training, and exercises.
- EW data bases.
- A library or repository for EW related information and techniques.

This technical strengthening of the JEWC is not intended to, nor should it, compete with the Service efforts which are primarily hardware oriented. The JEWC should focus on joint techniques, new combined technology-operational techniques, and test and evaluation support. It will require the JEWC to be charged with an on-going responsibility for these functions and not merely respond to the tasking of others as is now generally the case.

4.15 ESTABLISH A FORMAL COMMAND AND CONTROL RESEARCH PROGRAM AND CENTER

Many of the technology and operational trends which support aggressive actions to strengthen our Electronic Warfare capability also support the need for increasing our

application of technical skills to the function of command and control. The objective of this initiative is to accelerate that process at the research end of the creative process through the development of analytic concepts and rigor in the command and control field. It is completely consistent with the DSB report of 1978 on C^3 acquisition.

A modest Command and Control Research Center should be established at the Naval Postgraduate School as a companion organization to the NPS C^3 postgraduate activity. This center should perform and sponsor C^2 research which should include aspects of:

- Control theory
- Game theory
- Quality theory
- Utility theory
- C^2 modeling and simulation.

The center should not be capital intensive but rather should depend on the C^3 postgraduate facility, service test bed facilities such as exist at NOSC, and live field environments for their research facility needs.

In addition to the C^3 research aspects treated above, there is also a need for additional emphasis on the application of technical judgment to the development and acquisition of new command and control capabilities. However, these processes are fundamentally evolutionary in nature and this evolution which must be controlled from a position embedded in the command function. Therefore, strengthening these aspects is best accomplished by establishing a strong configuration management function within the

operational commands. The initiative treated elsewhere in this report to strengthen our command relationships could thus be an important assist in the command and control area.

THE UNDER SECRETARY OF DEFENSE

WASHINGTON D.C. 20301

RESEARCH AND ENGINEERING

3 SEP 1981

MEMORANDUM FOR SECRETARIES OF THE MILITARY DEPARTMENTS
DIRECTORS OF DEFENSE AGENCIES

SUBJECT: Review of DOD Laboratories - ACTION MEMORANDUM

In several recent examinations of the Defense research and advanced development process, the government laboratories which guide that activity, and the associated scientific and engineering work force, there is recurring evidence that the long-term health of the laboratory structure is in jeopardy. I am therefore initiating an intensive, high-level review of DOD laboratories to be undertaken under the direction of Dr. Robert Cooper. Dr. Cooper has asked that this effort be headed by Dr. Robert Hermann, 695-0578, who will be supported by a small ad hoc task force staff and a senior outside advisory group. The date for completion will be March 1, 1982.

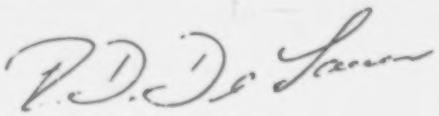
The objective of this effort is to identify those high leverage actions which we need to take to insure the long-term health of a sound DOD laboratory structure. At minimum, the product of this review will address:

- how the laboratories and their products are used,
- personnel practices,
- procurement practices,
- the laboratory management structure and process.

Your support and participation is requested in these areas.

. The Services should identify a qualified officer or civilian to serve as a member of the task force staff from September 1981 through March 1982.

. All should provide a point of contact to work with Dr. Hermann to facilitate laboratory visits, data gathering, and product review and coordination.



cc: Dr. George A. Keyworth

STUDY GROUP PARTICIPANTS

The following individuals were members of the study group:

Study Team Leader:

Dr. Robert J. Hermann	- Special Assistant for Intelligence to the Under Secretary of Defense for Research and Engineering

Army:

Mr. James A. Bender	- Director, Tech-Planning and Management Directorate, DARCOM
Mr. James E. Spates	- Ass't Dir. for Laboratory Activities Directorate of Army Research
Dr. Ravinder K. Jain	- Chief, Environmental Div. Construction Engineering Research Lab Champaign, Illinois

Navy:

Dr. Theodore A. Jacobs	- Dep. for Tech. Base, Office of Ass't Sec. of the Navy for Research

Air Force:

Col Richard H. Hartke USAF	- Vice Commander, Air Force Office of Scientific Research

DARPA:

Mr. David T. Petter	- Executive Ass't to the Director, Defense Advanced Research Projects Agency (DARPA)

In addition, the following individuals were of great assistance to the study effort.

Dr. Bernard A. Kulp	- Scientific Advisor to the Director of Laboratories Air Force Systems Command
Captain David F. Parrish USN	- Ass't Deputy Chief of Naval Material for Laboratory Management

INDUSTRIAL ASSOCIATION'S PARTICIPANTS

The study team asked the following four associates for their respective perceptions on the "DoD Laboratory Problem". In each case the association responded with well thought-out and poignant solutions to the problem. Their earnest participation is greatly appreciated. Much of their input directly impacted upon the study recommendations.

American Defense Preparedness Association

Dr. Elliott Axelband, Hughes ACFT

CHAPTER I

INTRODUCTION

The Senate Committee on Armed Services expressed concern, in a report dated May 31, 1984, "over the lack of growth in the Defense technology base over the past 2 years" and stated their belief that "the technology base programs represent our investment in future defense capabilities." Focusing on Department of Defense (DOD) support for university research, the Committee said that "DOD must do its share to maintain the excellence of our scientific infrastructure through strong support of university research." The Committee requested a report "on DOD activities and plans to support the United States infrastructure for science and engineering education and research." The Committee directed that the report "should address the role of DOD in the education and training of engineers and scientists for technologies used by DOD through (1) the support of university research, including independent research and development, (2) the interaction of defense contractors with the universities, (3) the use of fellowships, internships, and cooperative education, (4) the upgrading of university research instrumentation and facilities, and (5) the maintenance and development of technical skills in DOD laboratories. The report should also address how we, our NATO allies and Japan could work more effectively together in long term research to maintain our scientific and technical lead over

the Soviet Union." This report is submitted in response to that request.

In the long run, a strong United States science and technology (S&T) base is essential for maintaining the nation's military and economic position. The DOD S&T program is a major contributor to this effort to strengthen our national defense. Some relevant achievements accomplished or progress made in the program include:

1. Early development of lasers and incorporating their unique capabilities into weapons systems; the result is unprecedented precision in navigation and targeting.

2. Early development of integrated circuits and their application to mission critical capabilities in target detection and identification as well as weapon guidance.

3. Development of aircraft technology which provides substantially improved capabilities in maneuverability, flight and fire control, and firepower.

4. Significant progress in the development and fielding of chemical warfare protection which enables combat units to better survive and fight in a chemical warfare environment.

5. Development of the carbon-carbon composite material nosetip for the TRIDENT D-5 re-entry vehicle.

The DOD total S&T Program effort in FY 1985 is about $6.0 billion, of which about $0.9 billion is allocated to Basic Research, $2.3 billion to Exploratory Development, and $2.8 billion (including $1.4 billion for the Strategic Defense Initiative) to Advanced Technology Development.

The DOD S&T Program is carried out by three performers. In FY 1984, more than half of the DOD S&T effort was performed by industry, about a third by DOD in-house laboratories, and the balance by universities. Each performer plays an important role in the overall DOD effort, and the strong interrelationships and synergisms among the three components of the scientific infrastructure yield a major return on this investment. In view of the strong interrelationship among the three performers, this report considers efforts in all three areas to identify DOD needs, existing activities that should be strengthened, and new initiatives which have been undertaken or are being considered. This report also describes the major bilateral and multilateral S&T arrangements with our allies.

Analysis of the DOD S&T Program indicates that:

- Many important S&T contributions are being made toward increasing the technological warfighting capability of defense systems.

- o S&T work being performed by industry, universities, and in-house laboratories is of high quality, scientifically sound, and vital to our national defense.

The maintenance of future U.S. S&T capabilities will, however, require:

- o Additional funding in several S&T areas.
- o Measures to correct a decline in the supply of scientists and engineers to perform necessary defense-related research, particularly in universities and in-house laboratories.
- o Upgrading of university and in-house laboratory research instrumentation and facilities to assure high quality research.
- o New approaches in the contracting process to simplify interactions among government laboratories, industry, and universities involved in the S&T Program.
- o Cooperation and collaboration with our allies to improve our S&T posture.

This report describes some of the programs which are under way to address these issues. In addition, the FY 1986 budget request addresses some of these concerns. Continuing Committee support of the Science and Technology Program is necessary to the nation's future defense capabilities.

CHAPTER II
DOD SUPPORT OF UNIVERSITIES

A. INTRODUCTION

Overview

The subject of this chapter is the role that universities play in sustaining and strengthening the U.S. science and technology base, the scope and nature of existing DOD programs that support universities in that role, and additional measures that DOD may take to enhance that support. Subsequent sections of this chapter will address the DOD role in the direct funding of university research (Section B), the upgrading of research instruments and equipment (Section C), and the use of fellowships and other "people-oriented" programs to encourage career choices into areas of particular importance to DOD (Section D). Specific recommendations and future plans are summarized in Section E.

Granted the importance of these issues to DOD, it must nonetheless be recognized that maintaining an adequate science and technology base is a national priority with important economic as well as military implications. Thus, DOD cannot be expected to solve the attendant problems alone. Solutions must be broadbased in nature, encompassing all relevant government agencies, the private sector, and the universities themselves. This chapter focuses, however, on the relationship between DOD and universities.

Role of the Universities

The university establishment plays a uniquely important role relative to the strength of the nation's science and technology base. The universities are the source of future scientists and engineers. In addition, the research contributions of academia to society are

enormous. In the post-World War II era, universities have conducted most of the fundamental research that has spawned the technological innovations on which much of our economy and national defense are based today. Universities contribute approximately 70 percent of the scholarly papers appearing in prestigious science and technology journals. In addition to generating scientific insight and knowledge which forms the basis of future technological innovation, university research activities provide an essential environment for the development of future scientists and engineers. These activities enrich the professional experience of faculty and graduate students engaged in the training of technical manpower. Thus, support of university research produces multiple payoffs of inestimable value to society.

The success of the academic teaching and research enterprise involves a number of factors. They include a creative, dedicated faculty, sufficient laboratory and support resources, and an adequate supply of students, both graduate and undergraduate. Within the framework of these criteria, a number of challenges are associated with maintaining and/or upgrading the nation's technical education and research capacity:

o Faculty Shortages in Technical Fields: A survey conducted by the American Society for Engineering Education (ASEE) indicates an overall engineering faculty vacancy rate of 8.5 percent in 1983, with vacancy rates in electrical and computer engineering at 9.7 and 15.8 percent respectively. These shortages are primarily due to industry demand for talent in these areas. This demand tends both to decrease the number of persons seeking advanced degrees in technical fields and to lure those persons who do go on for a Ph.D. out of academe. Industry currently offers significantly higher salaries and superior laboratory equipment.

o Decline of U.S. Citizen Participation in Graduate Programs: The number of engineering doctoral degrees awarded to U.S. citizens by U.S. universities declined steadily throughout the 1970s and early 1980s, producing a net decline of 42 percent between 1968 and 1982, while the number of advanced degrees awarded to foreign nationals almost tripled during this same period. Nearly half of the engineering Ph.D.s now awarded go to foreign nationals. Little is known about the employment plans of foreign science and engineering Ph.D.s, but about half return to their home country. Whatever their plans, however, they generally cannot obtain U.S. security clearances and are not available for direct DOD employment and may be restricted as to DOD related work in universities and industry.

The decline in the number of American citizens pursuing advanced degrees can be attributed to several factors. First, as previously mentioned, marketplace demand for engineers is such that attractive job offers, providing immediate return on a student's investment in education, are luring bachelor degree recipients into industry. In addition, financial support is less available to graduate students than in the past. In 1983, the U.S. Federal government supported only 20 percent of the number of fellowships in 1968. Of those supported in 1983, only 1,600 were in engineering and science.

Finally, it must be noted that, as a result of demographic factors, the total number of 22 year olds in the U.S. will decline by approximately 17 percent by 1990. The decline in student population, already evident in many parts of the country, commensurately shrinks the pool from which future science and engineering talent can be drawn. Thus, unless student career preferences change substantially, the U.S. will graduate fewer scientists and engineers rather than the increased numbers required to maintain national technological competitiveness.

o Decline of University Research Laboratories: Estimates ranging up to $2 billion have been proposed as a requirement for replacing obsolete university research instrumentation. Laboratory facilities, especially instrumentation necessary to conduct research aimed at expanding the U.S. technology base, are becoming increasingly expensive. Establishing and maintaining these facilities is a very costly proposition for such equipment items as advanced supercomputers, large particle accelerators, various types of analytical instrumentation, imaging devices, and automated design and manufacturing hardware. Such equipment, nonetheless, is crucial for the conduct of meaningful research in important areas of science and engineering, and for the training of students.

DOD Support for Universities

As one of the first Federal agencies to recognize the essential role that U.S. colleges and universities play in the maintenance of U.S. technological leadership, DOD has maintained a strong relationship with the academic community; this relationship predates World War II. Since technological leadership is an essential component of military superiority, DOD has a major stake in maintaining the strength of U.S. science and technology.

o Direct Funding of University Research: U.S. universities are a major factor in DOD technology base activities. Approximately one half of DOD's Basic Research (6.1) is performed at universities ($405 million out of a total of $840 million in FY84). Support for universities is not limited to funding for Basic Research. As an additional important benefit, the resulting university research programs are a major factor in addressing the problems of the universities that were discussed in Section A.2. By providing the opportunity to perform fundamental research at the forefront of science and engineering, university research programs help to create a professional environment that can

attract and retain faculty and students. Past studies suggest that, on average, each $1 million of research program provides full or partial financial support for approximately 10-15 graduate students. On that basis, DOD provided financial assistance for over 4000 graduate students through its university research programs in FY84. As will be shown in Section C of this chapter, roughly $75 million worth of instruments and equipment were purchased by universities in FY84 through DOD research programs (counting a $30 million per year Defense University Research Instrumentation Program (DURIP) discussed below).

The DOD-university relationship has received strong emphasis during the last decade. In constant dollars, DOD funding for the performance of basic research at universities grew at an average annual rate exceeding 9 percent during the period 1975 to 1984. This is far better than funding for DOD technology base activities as a whole, which is still below 1965 levels in real terms as noted by Secretary Weinberger's memorandum to the Services dated August 9, 1984. As in the past, universities can be expected to compete effectively for future growth in DOD technology base funds. In the memorandum referred to above, Secretary Weinberger requested real growth for the technology base in the Defense Guidance for the FY 1987-91 Five Year Defense Plan. DOD continues to support that position. A more detailed discussion of direct funding of R&D at universities is provided in Section B of this chapter.

o University Research Instrumentation: DOD recognized the nature of the university research instruments and equipment problem well before formal studies were initiated. As suggested above, the fraction of university research contracts devoted to the purchase of instruments and equipment has been increasing--reaching approximately $45 million per year in 1984. In addition, specially targeted funds of $30 million per year are provided for large equipment purchases through the Defense University Research Instrumentation Program (DURIP). The availability

of modern instruments and equipment improves the quality of university research and enables universities to compete more effectively with industry for scientists and engineers. DOD will continue to address instrumentation needs through its research contracts and through special programs such as DURIP and the newly proposed "University Research Initiative" program elements discussed below. However, DOD cannot and should not address this problem alone. In view of the scope and magnitude of the problem, it must be addressed over a period of years in an interagency-private sector context. DOD instrumentation programs are discussed in Section C of this chapter.

o University Research Facilities: Although concern has been expressed about the condition of university research facilities (e.g., laboratory buildings), the dimensions of the problem have not been quantified. DOD is currently assessing the nature and scope of this problem. Results will be made available to the Committee as they are received. Once again, this is a problem which must be addressed over a period of years in a national context.

o Education Programs: The three Services have initiated a number of special programs designed to attract exceptional candidates to graduate study and to university faculty careers in areas of science and engineering of particular interest to DOD. These programs include graduate fellowships, summer faculty programs, special faculty chairs, a newly established Navy Young Investigators program, and programs to enhance professional interaction between university scientists and engineers and their colleagues in DOD laboratories and in industry. When considered in the context of stable growth for the technology base, increased availability of modern equipment in university laboratories, and the growing emphasis on similar programs at other federal research organizations, these "people-oriented" DOD initiatives represent a significant supplemental incentive to attract exceptional students and faculty to areas of interest to DOD. Funding levels for these programs

will be increased with the availability of funds through the "University Research Initiatives" discussed below. Other relevant special DOD programs are designed to attract more women and minorities to science and engineering research, and to provide incentives for high school students to consider technical careers. Some of these special programs are discussed in greater detail in Section D of this chapter.

o "University Research Initiative" Program Elements: In FY86 DOD plans to establish new research program elements that will be focused exclusively on the DOD/university relationship. Total proposed funding for the new program elements is $25 million in FY86, and $50 million in FY87. Additional growth is anticipated in future years. Each of the Services and the Defense Advanced Research Projects Agency (DARPA) will implement programs within these program elements to meet the priorities of their specific relationships with the academic community. Although the specific mix will vary from Service to Service, graduate fellowships, support for young investigators, purchase of research instrumentation, and support of special research programs will be included in the total DOD program for these program elements.

o DOD/University Advisory Groups: DOD has long recognized the value of the academic community as a source of expert advice. The Department maintains communications with people in the academic community, as individual consultants and as members of numerous advisory committees, on programmatic issues at all levels. To insure more effective communication with the academic community, specifically focused on issues at the policy level, DOD established the DOD/University Forum in 1983. The Forum has provided a mechanism for continuous dialogue between DOD and the academic community on issues of mutual interest. One significant, direct outcome of the Forum's activities during the past year was the establishment of a policy on the transfer of scientific information. The resulting clarification of DOD

policy establishes an appropriate balance between the conflicting imperatives of national security and open scientific communications.

B. DIRECT FUNDING OF UNIVERSITY RESEARCH

The Senate request for this DOD report on the technology base included the observation that "DOD investment in the technology base dropped by 40 percent from the mid-1960s to mid-1970s and today remains more than 30 percent below the mid-1960s level in real terms." This general pattern is illustrated in Figure B.1 which shows the history of DOD funding for basic research (6.1) since 1962. The corresponding funding history for exploratory development (6.2) is shown in Figure B.2.

During the past decade, DOD has taken major steps to reverse the past impact of the relative neglect of the technology base. As Figures B.1 and B.2 illustrate, funding in current dollars for both components of the technology base grew significantly during the late 1970s and early 1980s; nevertheless, neither component has returned to 1965 levels of support in real terms. In fact, in real terms, funding for exploratory development has been virtually constant for over a decade. In a memorandum to the Services dated August 9, 1984, Secretary Weinberger noted these facts and indicated that the Defense Guidance for the FY 1987-91 Five Year Defense Plan would request annual real growth in both components of the technology base. DOD still supports that position.

University research has been a major component of the growth in DOD technology base activities during the past decade. Table B.1 exhibits DOD 6.1 Research funds spent at or budgeted for universities by the Army, Navy, Air Force, and DARPA for the years FY74-86. Note that during the period FY75 to FY84 DOD spending for 6.1 Research at

universities grew at a real annual rate of 9 percent--higher than the annual growth of the total DOD 6.1 Research program.

Table B.1 shows only the DOD Research (6.1) funds going to universities. A similar break out of the university component of DOD Exploratory Development (6.2) funds is not readily available. To provide a point of reference, in FY83 a total of $102.3 million in DOD Exploratory Development (6.2) contracts went to universities as compared to $360 million for Research (6.1) contracts and grants. It should be noted that DOD funding for universities is not limited to Research and Exploratory Development.

DOD sponsors research and development at universities to ensure the advancement of fundamental knowledge that is necessary, in the long run, to maintain technological superiority. However, as will be noted in Sections C and D of this chapter, university research programs have other important impacts that have a significant effect on the future supply of scientists and engineers by attracting and retaining potential faculty and students, i.e., support for fundamental scholarly research, purchase of modern instrumentation, and financial support for thousands of graduate students.

C. INSTRUMENTATION

Background

Instrumentation is an essential element of modern research. Modern instruments with qualitatively superior capabilities for analysis and measurements can open new fields of scientific inquiry. In many scientific areas, access to the most advanced scientific instrumentation determines in large measure the extent to which scientists can work at the cutting edge of their field.

There has been a growing realization among the scientific and university communities, and in state and Federal government agencies and the Congress, that the condition of research instrumentation in U.S. universities declined significantly during the 1970s. The Association of American Universities (AAU) in a report to the National Science Foundation (NSF) in June 1980 concluded that the equipment being used in the top ranked universities has a median age twice that of the instrumentation available to leading industrial research laboratories, an additional factor in the attraction of potential faculty to industry.

A more recent survey by the NSF emphasizes this point. Data for the research instruments surveyed by the NSF were collected from a stratified probability sample of 43 universities selected from the 157 largest academic R&D performers. Inventories for all existing research equipment were obtained from institutions' central record-keeping systems and were sent to department heads for verification. More than 90 percent of both department heads and investigators responded. According to the survey, 25 percent of U.S. academic research equipment is classified as obsolete by the scientists who use it, whereas only 16 percent is characterized as being state-of-the-art. Results of the survey, based on 22,300 items in a 1982 research equipment inventory in computer and physical sciences and engineering, are summarized below:

Status	Age	Purchase Price
2% not in use	45% 1-5 years	58% $10,000-$24,999
16% state-of-the-art	20% 6-10 years	31% $25,000-$74,999
26% obsolete	31% over 10 years	11% $75,000-$1M
56% other		

The NSF study provides a more detailed breakdown by research area.

In terms of its capability to enable investigators to pursue their major research interests, department heads rated the adequacy of their research equipment as: excellent--8 percent; adequate--46 percent; and

insufficient--46 percent. More than 90 percent reported that "important subject areas" of research could not be performed in their units because of lack of needed research instrumentation. Thus, the state of university research instrumentation represents a national problem which deserves serious attention by government, private industry, and the university research community. The gap between the present university research instrumentation capability and that required to ensure maximum productivity by creative and innovative researchers has been estimated to be at least a billion dollars.

The instrumentation problem has been building for a period of 10 to 15 years. It reflects a combination of economic factors and funding patterns:

- The cost of equipment has risen considerably faster than inflation.
- The system of one to three year contracts in the $50,000 to $100,000 per year range with individual investigators tends not to lend itself to the purchase of equipment costing more than $50,000.
- Rapid advances in instrumentation technology are rendering research equipment obsolete at an ever increasing rate.

DOD Instrumentation Programs

Through its contacts with university researchers, DOD became aware of the instrumentation problem well before formal studies of the situation were initiated. DOD has encouraged investigators to include more of their equipment needs in proposals and emphasized that DOD does not set artificial limits on the amount of money that could be requested for instrumentation. This approach has been adequate to deal with

equipment needs up to the $50,000 range. However, there was a clear need for new money dedicated to the purchase of some of the more expensive items required to modernize university laboratories. These funds were provided in FY83 through the Congressionally approved DOD-University Research Instrumentation Program (DURIP).

DURIP provides $150 million over five years for university research equipment. Each of the three Services is programmed to spend $10 million per year. To date, $90 million has been spent on 652 awards going to 152 institutions in 47 states and Washington, D.C., Guam, and Puerto Rico. DURIP is having a major impact on the equipment needs of researchers doing work of interest to DOD. It will not, however, solve the whole university instrumentation problem. In the first year of DURIP, DOD received 2,500 proposals representing requests for $646 million worth of equipment. While some of these requests were for equipment to support research in areas not funded by DOD the first year response is nevertheless an impressive qualitative measure of the needs of the universities.

As already mentioned, DURIP is the most visible, but not the only, DOD response to the university instrumentation problem. In addition, each of the Services and DARPA have encouraged current and prospective contractors to make their equipment needs known so that many of the less expensive items can be purchased as an integral part of research program funding:

- The percent of the Army Research Office (ARO) contract program devoted to instrument purchases has increased steadily over the last decade so that in FY85 such purchases will represent approximately $6 million of the ARO contract research program.

- University related equipment purchases associated with the Office of Naval Research's Contract Research Program grew from $11.2 million in 1979 to $16.6 million in 1984.

- During the decade from 1975 to 1985, equipment funding by the Air Force Office of Scientific Research, during the normal course of its sponsored research program, increased from $2 million to $8 million per year.

- In general, 10 to 20 percent of DARPA's university program funds have been utilized for equipment. In 1981, DARPA initiated a modernization program targeted on obsolete equipment and the need for greater computational power. From 1981 to 1984, equipment purchases by universities using DARPA funds increased from $6.7 million to $16.8 million per year.

In certain cases, where the equipment necessary for major research efforts has been costly, specific provisions have been made for extraordinary purchases. Examples include the purchase of large main frame computers, semiconductor processing lines, molecular beam epitaxy and analysis chambers and ARPANET computational and communication facilities by DARPA, and an ongoing Office of Naval Research program to refurbish selected research vessels.

In FY84, in addition to the $30 million of special DURIP purchases, the three services and DARPA purchased over $45 million worth of research instruments and equipment for universities in connection with their ongoing research contracting activities.

D. EDUCATION PROGRAMS

Background

The ability of the United States to maintain superiority in broad areas of science and technology will largely depend on how well universities and colleges are able to recruit and train new scientific and engineering talent. Declining numbers of doctoral degrees awarded to U.S. citizens, coupled with the shortage of faculty in technical fields and the lure of industry employment, make the universities' task a difficult one.

The U.S. defense industry is a major employer of the scientists and engineers trained by U.S. universities and colleges. According to a recent National Science Foundation (NSF) study, the percent of U.S. engineers employed in defense activities will increase from 12 percent in 1982 to 15 percent in 1987. In 1982, DOD alone employed 105,000 engineers and scientists (3.6 percent of the national total). The NSF study projects rapid growth and shortages exceeding 10 percent of the workforce (by 1987) in disciplines particularly important to DOD: aeronautical engineers, computer specialists, and electrical/electronic engineers. This general conclusion is reinforced by projections of the American Electronics Association that predict an annual growth rate of 10.6 percent in the demand for electrical engineers through the late 1980s and a 16.5 percent growth rate in the demand for computer engineers.

Granted the importance of these trends to DOD, it must be emphasized that DOD and the defense industry are important but not dominant factors in the employment of scientists and engineers. Solutions must involve all relevant government agencies and the private sector.

The prospects for attracting greater numbers of outstanding students into careers in science and engineering in DOD are clouded by a number of important factors:

- Due to demographic factors, the number of students graduating annually from U.S. high schools during the 1980s is expected to drop significantly (approximately 17%). Together with the decreasing percentage of students studying mathematics and science, this trend is likely to have a major effect on the pool of young people who can be attracted into technical careers.

- High vacancy rates are reported for high school teaching positions in mathematics and the physical sciences. The number of people preparing to teach in these areas has decreased markedly.

- The number of Ph.D.s in engineering awarded to U.S. citizens by U.S. universities declined steadily throughout the 1970s and early 1980s, with a net decline of 42 percent between 1968 and 1982. Nearly half of all engineering Ph.D.s now go to foreign nationals. As indicated earlier, foreign engineering Ph.D.s, even if they remain in the U.S., generally cannot obtain U.S. security clearances and are thus not available for direct DOD employment. Reasons for the decline in U.S. citizens receiving graduate degrees include the lure of industry with existing pay differentials, the increasing cost of graduate school, and the decline in federal financial assistance.

DOD Education Programs

During the past decade, DOD has initiated numerous "people-oriented" programs designed to increase the supply of qualified technical personnel, both uniformed and civilian, and to attract exceptional candidates into careers in areas of particular importance to DOD. The complete set of programs is extremely diverse, ranging from secondary school level through undergraduate and graduate school. Some are designed for postgraduates and university faculty. Some relevant DOD programs are listed in Table D-1, including a number of programs that are supported with funds other than RDT&E funds. Additional information on selected programs will be provided below.

It is important to recognize that the formal programs listed in Table D-1 and those discussed below are supplemental to DOD's basic research programs. In addition to meeting important DOD technology base requirements, the direct funding of university research represents DOD's largest single education program. For example, a Navy study conducted in 1980 indicated that the Office of Naval Research (ONR) supported an estimated 2,200 graduate students (fully or partially) through its 6.1 contract research program. This study and similar estimates by others suggest that, on average, a million dollars of 6.1 university research funding provide financial support for approximately 10-15 graduate students. On that basis, the DOD university research program provided financial assistance for well over 4000 graduate students in 1984. In addition, the combination of research contracts and instrumentation programs provides a university research environment that is essential to retain university faculty and to attract graduate students.

DOD reaps several benefits from its supplemental support of science and engineering education. First, the programs attract highly-qualified students and support their training in areas of interest to DOD. Second, fellowship support increases the number of doctoral students who

then have the potential to train other students. Third, training programs provide a pool of recruits for the various DOD RDT&E programs. Finally, the programs provide a variety of intangible benefits ranging from the expansion of professional contacts and rapport with the various DOD laboratories to the generation of interest and excitement in science and mathematics at the elementary and secondary school levels. Highlights are provided below for selected programs.

HIGH SCHOOL APPRENTICESHIP PROGRAM

DOD established the DOD Science and Engineering Apprenticeship Program for High School Students in 1981 with the objective of encouraging and supporting careers in science and technology. The program has three major purposes: one, to stimulate stronger interest in careers in science and engineering among high school students; two, to establish individual student/mentor relationships between students and active researchers; and three, to strengthen the nation's efforts to recruit and sustain careers in science and engineering, consistent with affirmative action program goals and objectives. Although the apprenticeship program applies most directly to DOD laboratories, it can also be used by the service research offices through their contract-supported principal investigators at universities.

SELECTED ARMY EDUCATION PROGRAMS

The Army has programs in science, mathematics, and engineering education at the secondary, undergraduate, graduate, and postgraduate levels.

Pre-College Education Programs. (i) The Junior Science and Humanities Symposium (JSHS) Program exposes 7,500 secondary students each year to leading scientists in the academic, industrial, and government communities. (ii) 60,000 students annually participate in

more than 280 regional, state, and International Science and Engineering (ISEF) Fairs. (iii) Eight talented students are selected competitively from over 400,000 high school participants to represent the U.S. at the annual International Mathematical Olympiad (IMO). (iv) The Uninitiated Introduction to Engineering (UNITE) program provides a select group of socially - and economically - disadvantaged high school students with four weeks of summer instruction and guidance by cooperating universities and Army laboratories. (v) The Research and Engineering Apprenticeship Program (REAP) can extend over several summers and offer mentor/apprentice training for disadvantaged youngsters by university professors. (vi) An intensive, four-week program involving digital logic, microprocessors, robotics, and programming is available in Computer Related Engineering and Science Studies (CRESS).

Undergraduate Educational Programs. The Army's Reserve Officer Training Corps (ROTC) program includes 12,000 students at over 300 universities; recent selections have emphasized science, mathematics, and engineering. Also, the Army has a very active co-op work/study arrangement with many colleges and universities.

Graduate Level Educational Program. Over 800 research contracts with universities throughout the United States support, as a byproduct, many graduate students working on the contracts. In addition, last year, the Army awarded 35 graduate fellowships in computer science, electronics, modern optics, hypersonic aeromechanics and aerodynamics, and biogenetic engineering under the Army Fellowship Program.

Special Educational Programs. Seventeen historically black colleges (HBC) are involved in a special Army effort to sponsor mathematics, engineering, and science research at HBCs; about $1.4 million per year is involved. The Summer Faculty Research and Engineering Program (SFREP) offers 10-week summer appointments in Army laboratories to selected university faculty members; 24 Army

laboratories participate. The Army has a similar program for high school science and mathematics faculty that involved 90 teachers in first summer of the program.

Postdoctoral Program. Working with the National Academy of Sciences, the Army has about 55 National Research Council Fellows working in several Army laboratories on postdoctoral research. This program is available to new doctoral graduates as well as to more senior researchers at colleges, universities, non-profit research institutes, etc. The program fosters interaction between Army and civilian scientists and engineers, and it has resulted in Army recruitment of many capable young researchers.

SELECTED NAVY EDUCATION PROGRAMS

The Navy supports science and engineering education at all levels. Several of these programs are run by or in conjunction with Navy laboratories because of their direct need for highly trained personnel.

At the pre-college level, the Navy has programs for hiring science and engineering apprenticeship students at laboratories in the summer. ONR encourages university contractors to involve high school students on research projects. In FY 1983, 335 students were supported under these programs. In addition to participating in regional and state science and engineering fairs, the Navy offers scholarships and other awards in the Navy National Science Awards Competition and the International Science and Engineering Fair.

At the college undergraduate level, the Navy supports three programs: the ROTC Science and Engineering Program, the Co-op Education Program, and the Federal Junior Fellowship Program. In FY 1983, these programs had approximately 7,300 participants.

The Navy supports several significant educational programs at the graduate level. These include the ONR Graduate Fellowship Program, the Co-op Education Program, and the Military Graduate Education Program. The ONR Graduate Fellowship Program is directed toward increasing the supply of U.S. citizens trained in areas of science and engineering of particular importance to current and future naval technology. Started in FY 1982, this program currently supports 40 new fellows per year, who pursue doctoral studies in electrical engineering, computer science, naval architecture, applied physics, material science, mechanical and aerospace engineering, mathematics, and oceanography. Funding for this program is planned to grow to over $4.5 million by FY 1989, thereby enabling the selection of 50 new ONR fellows per year. This represents a 20 percent increase over the present level.

The Navy supports postdoctoral training at Navy laboratories and under research contracts at universities. The Navy awards Postdoctoral Cooperative Research Associateships through the National Research Council. These associateships can be used at the Naval Research Laboratory (NRL), Washington, D.C. and the Naval Ocean Research and Development Activity (NORDA), Bay St. Louis, MS. These competitive awards provide opportunities for doing basic and applied research on-site at NRL or NORDA. A program sponsored by the Office of Naval Technology provides similar opportunities for thirty postdoctoral research fellows each year at the other Navy laboratory centers.

In addition to student support, the Navy provides faculty support. Under the Summer Faculty Research Program, science and engineering faculty members from universities and colleges spend ten weeks in the summer conducting research at Navy laboratory centers. For the last three years, over one hundred university faculty members have entered this program each summer. Participants work with professional peers on research tasks of mutual interest. Follow-up programs have been found to occur between the laboratories and the faculty members in

57-279 O - 87 - 43

about 30 percent of the cases. A second program supports research chairs at the U.S. Naval Academy, the U.S. Naval Postgraduate School, the Massachusetts Institute of Technology, and the University of Michigan. The Navy also finances visiting professorships to the U.S. Naval Academy and the U.S. Naval Postgraduate School.

ONR plans to initiate a new program in FY 1985 to identify and support exceptional young investigators who are in tenure track positions at U.S. universities. The ONR Young Investigator Program is designed to encourage younger researchers to take an active role in naval research. ONR will invest $2.0 million in this program in FY 1985.

In addition to its formal educational programs, the Navy also has the Historically Black Colleges (HBC) Council. The Council is an officially established ONR body whose primary purpose is to facilitate relationships between HBC institutions and ONR that may eventually lead to greater HBC participation in the ONR Contract Research Program (CRP). As a result of this and other efforts, ONR spent $2.4 million with HBCs in FY 1984.

SELECTED AIR FORCE EDUCATION PROGRAMS

The Air Force is supporting science and engineering education through officer commissioning and graduate education programs, civilian personnel programs, and a number of special programs associated with basic research.

Under its officer commissioning programs, in FY 1985 the Air Force will provide 7,500 ROTC scholarships, of which 85 percent are for S&E students. It will also enroll about 400 airmen in the Airman Education and Commissioning Program, of which about 90 percent will be S&E students, and 75 students in the College Senior Engineering Program. In FY 1985, about 525 officers will enter graduate S&E programs.

The Air Force Laboratories, Centers, and Product Divisions also support programs to: (1) introduce high school students to Air Force technical careers; (2) employ undergraduate S&E students in co-op, stay-in-school, and summer hire programs; and (3) support the technical upgrading of civilian S&E employees through short-term and long-term full time training programs.

At present, about 60 percent of the Air Force basic research program is under contract at universities. This research supports an estimated 1,000 to 1,200 graduate students through research assistantships. In addition to this general support, AFOSR and the Air Force laboratories provide research and educational opportunities for graduate students, post doctoral scientists and engineers, and university faculty through special programs that support research on problems of interest to the Air Force.

The Air Force Office of Scientific Research (AFOSR) supports four graduate student assistantship programs that are focused on research areas of critical interest to the Air Force. The Air Force Thermionic Engineering and Research Program (AFTER) is focused on microwave tube research, a technology that electrical engineers supporting the vast consumer electronics industry have largely vacated. The Advanced Composite Structures Program is aimed at attracting students to research in composite structures and composite mechanics. The Air Force Research in Aircraft Propulsion Technology Program (AFRAPT) has the objective of attracting students to research in aircraft propulsion technology. The Manufacturing Sciences Program has the objective of attracting students to research in manufacturing techniques associated with aerospace vehicle assemblies. Total funding for these four programs increased from $2.5 million in FY 1982 to $4.44 million in FY 1985.

AFOSR supports two programs which bring university faculty members and graduate students into Air Force laboratories for ten weeks during

the summer. The Summer Faculty Research Program (SFRP) is designed to develop the basis for continuing research of interest to the Air Force at the faculty member's institution. In addition to the ten week summer research program, funding is also provided to allow about 50 percent of the researchers (on a competitive basis) to continue the research at his or her home institution. The Graduate Student Summer Support Program (GSSSP) allows outstanding graduate students to spend ten weeks at an Air Force laboratory conducting research while accompanying faculty members selected under the SFRP. Funding for these programs increased from $1.5 million in FY 1982 to $4.4 million in FY 1985.

The Air Force supports several programs which allow postdoctoral scientists and engineers to spend a year conducting research at Air Force laboratories on problems of their own choice that are compatible with research interests of the sponsoring laboratories. The Air Force Systems Command/National Research Council Resident Research Associateship Program and the University Resident Research Program are supported by AFOSR but with researchers placed at various participating laboratories. The Air Force Geophysics Laboratory and the Air Force Weapons Laboratory also support, respectively, the Geophysics Scholar Program and the Weapons Laboratory Scholar Program within their own laboratories. Total funding for these programs increased from $1.6 million in FY 1982 to $2.9 million in FY 1985.

AFOSR is engaged in a special initiative utilizing workshops and focused advertising to make Historically Black Colleges (HBCs) aware of opportunities in Air Force research and development, and to recruit faculty members and graduate students from HBCs for participation in the SFRP and GSSSP. In addition, under a grant from AFOSR, the Tuskegee Institute is conducting a summer research apprenticeship program for minority high school students.

E. RECOMMENDATIONS AND FUTURE PLANS

Funding of University Research

Significant real growth of the DOD technology base is required to ensure the advancement of fundamental knowledge necessary, in the long run, to maintain military and economic parity through technological superiority. It must be noted that funding for university research also addresses many of the problems associated with the future supply of scientists and engineers by creating a more attractive academic environment for both faculty and students, providing financial assistance for graduate students, and supporting the purchase of modern instrumentation.

- The Congress should authorize and appropriate the President's FY 1986 budget amounts for the DOD technology base at the requested level.

- Congressional approval for the FY 1986 budget should include the establishment of "University Research Initiative" program elements, with funding at $25 million in FY 1986, devoted exclusively to university programs.

- The current Defense Guidance specifies real growth for the Research and Exploratory Development programs for the years 1987-1991. This growth should be viewed as the minimum growth rate for the direct funding of R&D that is required to restore the health of the technology base. Additional funds should be provided to exploit technological opportunities and to support special programs that supplement and leverage the direct funding of research.

- Funding for the new "University Research Initiative" program elements should be increased to a total of $50 million in FY 1987. DOD should seek additional growth in future years.

- Additional funding beyond the base program described above, if available, would be used by the Services and DARPA in areas that would provide significant leverage for the base level of DOD research funding. To give but one example, the conduct of research at the frontiers of science and engineering requires access to the most advanced numerical and symbolic computational facilities. Providing DOD contractors with access to such facilities would significantly increase their productivity in many key research areas.

Research Instrumentation

- As documented in Section C, in addition to the specially targeted $30 million per year Defense University Research Instrumentation Program (DURIP), a very significant fraction of the funds provided to universities through DOD research contracts and grants is targeted for the purchase of research instruments and equipment (roughly $45 million in FY 1984). DOD will continue to emphasize such purchases as an integral part of its contract research program.

- If approved by the Congress, the purchase of research instruments, either directly or through special research programs, will be one of the potential uses for funds in the new "University Research Initiative" program elements.

- DOD will continue its highly successful DURIP program to update university research instrumentation. Funding for this program is currently scheduled to expire after FY 1987. The magnitude of the response to the DURIP program has confirmed the perception that there is a substantial need for modern instruments in university research laboratories. DOD cannot and should not address this problem alone. The problem should be addressed in an interagency context.

Research Facilities

- DOD has an obvious interest in the condition of the research facilities available to the universities who play an essential role in DOD technology base programs. A separate study is currently under way to determine the nature and scope of this problem for DOD contractors. Preliminary studies conducted by others suggest a problem of great magnitude. Once again, DOD cannot and should not address the problem alone. The need for a multi-year, interagency approach is even greater in the case of facilities.

Education Programs

- As documented Section D, the DOD Services support a variety of programs designed to attract future scientists and engineers at all levels, ranging from high school to postgraduate study. Additional programs have been established to attract bright young scientists to academic careers and to encourage professional interaction between university scientists and engineers and their colleagues in DOD and industrial laboratories.

CHAPTER III

DOD IN-HOUSE LABORATORIES

A. INTRODUCTION

This chapter addresses factors essential to the effective performance of the Department of Defense in-house laboratories. Its aims are threefold:

- To ensure a current understanding of the roles and posture of the laboratories.
- To address representative issues critical to the vigor of these laboratories.
- To highlight approaches the DOD is using to better ensure the maintenance and development of technical skills in its laboratories.

The perspective is one of overview; the topics are highly selective. Individual laboratories are not discussed. Resource breakouts are kept to a minimum. The objective is to provide information for the Congress in an orderly form to highlight areas of action conducive to ensuring a vigorous defense science and technology community.

B. UNDERSTANDING THE LABORATORIES

Understanding the DOD laboratories is an essential part of actions to address current and future defense capabilities. From this understanding can come change which will assist the laboratories in meeting their vital roles. The current atmosphere of reduced U.S.

direct involvement in military conflicts offers an opportunity to introduce improvements into the laboratories with minimum disruption of critical activities. The high stakes involved in our international technological markets and in the national security competition with the Soviet Union make it essential that increased attention be given to:

- Better ensuring the relevance and quality of the work in the laboratories.
- Improving staff and their facilities and equipment.
- Maintaining and improving the quality of technical leadership and management of these laboratories.
- Providing this leadership the authority and flexibility to effectively manage their resources.

C. PROFILE

There are approximately 72 DOD in-house laboratories, some large, some small, performing work in the physical, life, and behavioral sciences in support of military and civil works programs of the DOD. They constitute a large investment of dollars and manpower. The acquisition cost of real property and equipment exceeds $4.0 billion. Some 27,500 scientists and engineers conduct the diverse activities of the laboratories. An annual cash flow greater than $7.9 billion is involved, with nearly two-thirds of that being research and development. About 40 percent of these R&D funds are retained by the laboratories to carry out work directly with their own personnel, the remainder being contracted largely to industry and universities. The non-R&D portion of the laboratories' funds are predominantly procurement monies that are used to achieve first acquisition of material systems and associated procurement support activities.

D. ROLES

The DOD in-house laboratories have become increasingly important to DOD RDT&E and Procurement programs. Recent emphasis in these areas increases the cruciality of their performance. As major participants in the technology base and in the systems development and acquisition process, the laboratories must undertake workload to respond to national need and programming to:

- Direct substantial R&D effort toward the longer term technological opportunities and deficiencies--particularly through the vitalization of our technology base, the stimulation of prototyping and the use of mature U.S. and Allied technology, and the reduction of intelligence asymmetry and "technological surprises" in the face of a determined and well supported Soviet competition. This effort includes the monitoring, assessment, and evaluation of the science and technology base in terms of potential for military utilization.

- Provide engineering support to obtain lower cost for weapon systems and equipment in production, operation, and support.

- Conduct advanced development and full-scale engineering development as appropriate.

- Achieve weapons equipment improvements which reduce the impact of projected manpower constraints.

- Provide scientific and engineering services and support to the operating forces.

- Develop, operate, and maintain major R&D facilities to meet specific needs unique to national defense requirements.

- Conduct mission analysis to identify system needs and deficiencies, both current and future, and determine preferred courses of action.

In accomplishing these functions, it should be stressed that a primary purpose of the laboratories is to develop and nurture new technologies to support their missions. The importance of this role for the in-house laboratories--the extension, development, and constant improvement of the technology base underlying all future development efforts--is fundamental. Unfortunately, this function is easily lost in the flood of product improvements, "quick-fixes" and concern over current operational problems--often the result of previous neglect to the technology base. It is imperative that the laboratories remain on the cutting edge of technologies critical to future military systems, both through their own research programs and through fostering and synergizing the results of such research, in the academic and industrial segments of the research community.

Further underscoring the need for competent and creative DOD in-house laboratories are reasons such as the following:

- The maintenance of national competence during peacetime, as well as times of conflict, in those areas of technology peculiar to military needs.

- The necessity for maintaining a continuity of effort, free from excessive commercial pressures, directed toward the conception and evolution of advanced military systems and equipment.

- The need for competent in-house skills to carry concepts through the planning, programming, and budgeting process for support of direct in-house work and for potential contract placement, monitoring, and assessment, and the ability to execute R&D as appropriate.

- The requirement to have available to the DOD a fast-reaction capability to solve critical, immediate problems that arise in connection with existing operational weapons systems and other items, and when unexpected combat situations are encountered (such as some of those experienced in Southeast Asia and the Middle East).

Figure 1 shows ten major goals and objectives for the DOD in-house laboratories. Secondary roles include such things as providing a training base for junior and senior military personnel, and for civilians who can transfer to headquarters and to nonlaboratory DOD elements involved in science and technology activities.

Figure 2 shows the major required in-house functions for DOD R&D and associated organizations involved in fulfilling their roles. Accordingly, the DOD has nurtured its laboratories for several decades to establish an environment conducive to the exchange of technical information and the exercise of judgment tailored to effective overall management. The bonds integrating the laboratories with a wide array of DOD research, development, and acquisition activities are complex and important.

FIGURE 1

DEPARTMENT OF DEFENSE
GOALS AND OBJECTIVES FOR RESEARCH AND DEVELOPMENT LABORATORIES

1. Ensure the maintenance and improvement of national competence in technology areas essential to military needs.

2. Avoid technological surprise and ensure technological innovation.

3. Maintain a continuity of effort, free from excessive commercialization pressure, directed toward the conception and evolution of advanced military material and support technologies.

4. Pursue technology initiatives through the planning, programming, and budgeting process; allocate work among private sector organizations and government elements.

5. Act as principal agents in maintaining the technological base of DOD.

6. Provide material acquisition and operating system support.

7. Have available a fast-reaction capability to solve critical, immediate technical problems that arise when unexpected operational situations are encountered.

8. Stimulate the use of technical demonstrations and prototypes to mature and exploit U.S. and allied technologies.

9. Carry out activities having high technological risk or requiring intensive resource investment not available from the private sector.

10. Interface with the worldwide scientific community; provide support to other government agencies.

SOURCE: Department of Defense

FIGURE 2

MAJOR DEPARTMENT OF DEFENSE RESEARCH AND DEVELOPMENT FUNCTIONS

1. BASIC RESEARCH - Increasing knowledge and understanding in fields directly related to long-term national security needs.

2. EXPLORATORY DEVELOPMENT - Developing and evaluating technical feasibility for solving broadly defined problems.

3. ADVANCED DEVELOPMENT - Systematic knowledge application toward production of useful materials, devices, systems, or methods.

4. ASSESSMENT OF SCIENCE AND TECHNOLOGY BASE - Continuous monitoring, assessment, and evaluation in terms of potential for military utilization.

5. MISSION ANALYSIS - Identification of systems needs and deficiencies, current and future, and determination of preferred courses of action.

6. CONCEPT EXPLORATION/SYSTEM VALIDATION - The feasibility study, development, and refinement of system concepts in response to military needs.

7. FULL-SCALE ENGINEERING DEVELOPMENT - Hardware engineering for Service use prior to approval for procurement.

8. ENGINEERING IN SUPPORT OF PRODUCTION - Periodic testing of production hardware, failure analysis, establishment of corrective actions, technical documentation control, and review of proposed production changes.

9. TEST AND EVALUATION - Determination of whether systems meet established performance objectives prior to release to production.

10. MAJOR RDTE FACILITIES - Facilities to meet specific needs unique to national defense requirements.

11. SERVICES AND SUPPORT TO OPERATING FORCES - Includes installation and testing, design deficiency correction, system improvement/retrofit, training, and logistic support.

SOURCE: Department of Defense

E. ISSUES

DOD laboratory management involves several issues which in the end merge into a single issue--how can the DOD increase the effectiveness of its personnel and funding resources for laboratories. This is, of course, much too large an issue to be taken in one bite. Ths single problem, insofar as the laboratories are concerned, may be viewed as consisting of the following primary issues:

- o Achieving balance between available manpower and tasking within funding constraints.
- o Obtaining adequate flexibility for management.
- o Ensuring proper degree of intra- and inter-laboratory coordination.
- o Providing appropriate performance incentives and work environment.
- o Developing a program structure conducive to realization of goals.
- o Maintaining a proper mix of in-house and contract R&D.
- o Developing adequate mechanisms for performance assessment.
- o Changing priorities
- o Making long-term projections

These and other similar interests lie at the heart of the maintenance and development of the laboratory infrasturcture and the

general health of the defense technology establishment. What is needed is full recognition that continuous concerted attention and assistance is essential.

F. CURRENT SITUATION

The DOD has been and is developing approaches that will further improve management of its laboratories. These actions are in various stages of advancement, some establishment, some evolving. Included in these actions are two dominant interrelated thrusts:

- The establishment in 1979 of the DOD Laboratory Management Task Force (LMTF). The LMTF is a standing working group chaired by the Office of the Secretary of Defense involving senior laboratory managers from the three military departments. This group has aggressively addressed a variety of laboratory-oriented issues and has obtained major improvements in policy and procedures. It continues to be a model of joint cooperation and action to focus on the welfare of the DOD laboratories.

- Renewed commitment to addressing the imposing challenges to U.S. technological superiority and the addressing of hard issues underlying the vitality of defense science and technology.

These thrusts and associated efforts directly affect the laboratory issues of image, operations, and long-term perspectives. They have resulted in management initiatives to:

- Provide laboratory managers with the responsibility, authority, and flexibility to manage laboratories and technical programs through use of broad guidelines and without overlapping controls.

- o Ensure competency of personnel by:
  - Recognizing clearly that the most valuable resource of the laboratories is the capability, skill, and creativity of their personnel.
  - Providing for personnel stability, challenging work, and meaningful incentives.
  - Providing for equal opportunity for career development, training, promotion, recognition, and reward.
- o Upgrade facilities and equipment by:
  - Removing limitations which constrain modernization of laboratories.
  - Promoting productivity, energy efficiency, and cost avoidance through policies which provide for modern facilities and equipment.
  - Basing replacement policies on practices that befit the business venture nature of research and development activities.
- o Provide effective procedures for procurement and acquisition by:
  - Providing laboratories with the authority and capability to make procuremnts and acquisitions in a timely and efficient manner.

- Ensuring technical acceptability in contractor performance.

o Achieve continuing assessment and accountability by:

- Conducting periodic evaluations to assess the health of the laboratories, the quality and quantity of their contributions, and their performance against the public's legitimate expectations of efficient and effective use of personnel and financial resources--including the vigor of their partnership with industry and the academic community.

G. PERSONNEL - A CENTRAL CONCERN

Over the years there have been numerous high level review groups both internal and external to the DOD, which have examined the state of DOD in-house laboratories. These panels have found that the laboratories are necessary and perform a vital function reasonably well. They do this despite conditions which make such performance extremely difficult. Each panel has recommended actions to mitigate the negative environmental factors identified. There is a consistancy across these recommendations from panel to panel, and from year to year, suggesting that serious problems degrading the laboratories performance remain unchanged despite repeated identification. Representative major review panels since 1980 have included:

o DOD Laboratory Management Task Force - report of management constraints on the Laboratories (1980)

o Defense Science Board Summer Study of the DOD Technology Base (1981)

- Joint Logistic Commanders Study of Engineers (1981)
- Defense Science Board University Responsiveness Study (1982)
- Independent Review of DOD Laboratories (1982)
- Army Science Board Summer Study of Army Military and Civilian Scientists and Engineers (1982)
- DOD Laboratory Management Task Force Study of Scientists and Engineers in DOD Laboratories (1982)
- National Academy of Sciences Report on the Professional Environment in Army Laboratories and its Effect on Scientific and Engineering Performance (1983)
- White House Science Council Federal Laboratory Review Panel (Packard Committee) (1983)
- Report to the President on implementing the recommendations of the White House Science Council Federal Laboratory Review Panel (1984)

Major recommendations for corrective actions may be summarized as:

- Aggressively recruit scientists and engineers (S&Es).
- Adjust S&E pay scale to meet services' needs and market competition.
- Develop a systematic integrated pre-college through postdoctoral fellowship/career development program to

attract, retain, nurture, and develop S&E personnel and skills identified as critical to service needs--include informal training, such as conference attendance.

- Modernize laboratory equipment and facilities--review on regular basis, priorities requirement and implement.

- Remove personnel and high grade ceilings--let mission and program dollars drive personnel levels, holding laboratory directors responsible.

- Increase support personnel to S&E ratio--which will enable S&Es to better perform their critical roles.

- Provide laboratory directors with maximum possible flexibility to manage resources and review results for their respective areas of responsibility.

- Establish a scientist and engineer personnel system which includes flexibility to rapidly employ both permanent and temporary senior specialists.

- Improve links with universities--develop cooperative arrangements, centers of excellence, and significantly increase basic research in the university sector.

One of the major recommendations made by the White House Science Council's Federal Laboratory Review Panel was to create a scientific/technical personnel system that would be independent of the current Civil Service system. Since October 1983 an interagency group under the Federal Coordinating Council for Science, Engineering, and Technology has been working on that recommendation. What is needed is a system which would:

- o Permit agencies to include scientific and technical personnel in the new personnel management systems;

- o Simplify job evaluation and remove covered positions from the position classification requirments of 5 U.S.C., chapter 51;

- o Provide flexibility to develop salary structures which ensure a competitive position in the labor market and which reflect the hiring and pay policies needed to attract, retain, and motivate a highly qualified scientific and technical work force;

- o Base pay increases on performance, not longevity;

- o Allow limited waiver of pay cap for up to five percent of specially qualified scientific and technical personnel;

- o Provide for performance and special awards and remove pay cap for lump-sum awards; and

- o Permit the creation of a Senior Scientific and Technical Personnel Service.

Modern research facilities, equipment, and instrumentation are also required to attract, retain and motivate the best scientists and engineers. Each year, the in-house laboratories compete for the limited funds budgeted within each Service for military construction (MILCON) projects required for laboratory modernization and associated equipment. The competition is keen and many projects and equipments deserve support. During FY86, DOD will assess in-house research facility and instrumentation requirements. These needs will be reflected in future budget requests; an effort paralleling the multi-

year upgrading of university laboratories may be called for. As an example, the DOD laboratories critically need improved access to supercomputer technology; options are being explored.

Another area of serious concern is contracting for technology support. The procedures currently existent are, at best, usually cumbersome and lengthly. As currently configured they have a negative impact on the efficiency and effectiveness of laboratory science and engineering personnel. This situation is particularly critical in the area of evolving science and technology.

H. DOD POSTURE AND RECOMMENDATIONS

The foregoing sections provided a highly condensed summary of representative DOD involvements to address the issue of the maintenance and development of technical skills in the DOD laboratories. This summary clearly demonstrates a heightened awareness on the part of top management, in the Office of the Secretary of Defense and in each of the military departments, of the need to focus on laboratories and their institutional needs. As a result of this intensified managerial attention, numerous improvements have been made and action to achieve others is in progress.

To assist DOD in addressing the effective mission performance of in-house laboratories, we need an alternative personnel management system to improve the quality of scientific and technical personnel. This system would improve our management flexibility and ability to attract, retain, and motivate a qualified scientific and technical workforce.

In summary the DOD must address barriers to good laboratory management, especially in the following areas:

- Personnel - We need a performance-based personnel management system for Scientists and Engineers. It should give supervisors a major role in the position description and classification of people.

- Facilities - We need an aggressive program for 15 years to modernize and update laboratories, facilities and instrumentation.

CHAPTER IV

DOD-INDUSTRY INTERACTIONS

A. INTRODUCTION

This chapter addresses the DOD research and development program performed by U.S. industry. This represents approximately 68 percent of the $31 billion FY 1985 research, development, test, and evaluation program (RDT&E) funded by DOD. Differences between R&D and systems acquisition contracting needs are discussed broadly. Specific DOD initiatives with respect to large corporations (Independent Research and Development-IR&D) and small corporations (Small Business Innovative Research-SBIR) are examined. Simplification of the contracting process for small R&D contracts is recommended; this would require legislative action.

B. IMPORTANCE OF INDUSTRY TO NATIONAL DEFENSE

A strong free enterprise economy and industrial base--here and abroad--are the essential underpinnings of our defense posture. Investment in our technology base and maintenance of our technological strength are critical to the long term security of the U.S. and our allies. Success in achieving the military posture we need is highly dependent on modern technology and its coordinated application.

DOD cannot effectively field this technology without an increasingly efficient industrial base.

C. CONTRACTING ISSUES

DOD contracting for R&D as well as systems acquisition is defined through public law, implemented through the Federal Acquisition Regulations, and further interpreted by Service regulations. Service interests are primarily in systems acquisitions involving large dollar amounts that are subject to considerable Congressional scrutiny. Examples of such systems include the B-1 aircraft, the TRIDENT submarine, and the M-1 tank. These systems acquisitions are characterized by large numbers of items generally integrated by a major contractor with many subcontractors. The contracts are typically competitive, multiyear procurements encompassing provisions for large numbers of items and many spares for subsystem replacement or maintenance.

The DOD Science and Technology program, by contrast, is quite different in content and approach. In the DOD laboratories, scientific and engineering personnel are searching for new innovative ideas and better ways to solve persistent problems either of which may lead to totally new capabilities. Laboratory contracts, on the average, are much smaller (in dollar value) than system contracts and are likely to

be one-of-a-kind demonstrations rather than large numbers of similar items. This contrast suggests that there may be a need for special contracting provisions for the laboratory community.

A review of Air Force data for basic research shows that the average contract or grant is approximately $95,000 per year. A similar review of exploratory development gave an average contract size of approximately $195,000 per year. Although the Army and Navy did not collect data in a similar manner, it can reasonably be assumed that most contracts in the Science and Technology (S&T) program are less than $300,000 per year. Using $300,000 as a point of reference gives about 10,000 procurement actions for the FY 1985 DOD program in research and exploratory development ($3,380 million). This simple calculation gives an idea of the contracting workload generated at the laboratories in a typical year. It also is indicative of the potential benefits of the simplification of contracting procedures.

In recent years, there have been significant changes in procurement law relating to competition and innovation. They have generally lengthened the contracting process. A quick review of these changes yields the following added requirements to the contracting process:

a. Small business subcontracting plans - required in contracts/modifications expected to exceed $500,000 with the potential for subcontracting (small business concerns are exempt).

b. 30 day delay for RFP issuance for proposed acquisitions in excess of $10,000.

c. Requirement to allow at least 30 days for proposal preparation.

d. Approval of the Head of the Contracting Activity on all proposed sole source acquisitions over $500,000 (to be increased to $1,000,000 in April 1985).

e. Lowering of the threshold for certified cost and pricing data from $500,000 to $100,000.

These changes have generally lengthened the contracting process for the technology base.

To fulfill their missions, DOD laboratories must keep abreast of new developments in science and technology. This is an ongoing process, made more challenging as the pace of R&D innovation, both foreign and domestic, accelerates. Activities pursuant to this objective range from the review of industry IR&D programs to soliciting new ideas from universities and industry including small business concerns. The IR&D program and the Small Business Innovative Research program are discussed in Sections D and E of this chapter. The special instrumentation program for universities has already been discussed in Chapter II.

The discussion thus far has developed a perspective for laboratory technology, but leads to some philosophical questions which should be considered, i.e.,

a. Should there be special procedures for small contracts?

b. Should there be special procedures for DOD (and, perhaps, all Federal) laboratories for the purpose of stimulating technology transition and special cooperative efforts?

D. INDEPENDENT RESEARCH AND DEVELOPMENT (IR&D)

IR&D, as defined by DOD, is a contractor-funded R&D program. The R&D efforts are chosen and conducted by the contractor to maintain and improve his technical competence and competitive position in the marketplace. Thus if a company must continually come out with new and updated products to remain competitive, it is advantageous to conduct an IR&D program to develop these new or improved products. Manufacturers of automobiles, minicomputers, word processors, steel, aluminum, plastics, air conditioners, and refrigerators are typical examples of commercial sector companies that would be likely to conduct IR&D programs. In any given year, companies recover IR&D program costs through sales of their products. These products could be end items, such as airplanes, boats, and automobiles, or the results of research performed on R&D contracts. Likewise, companies that develop weapon

systems or subsystems must conduct IR&D programs to remain competitive in the DOD market place.

DOD has the following objectives for the IR&D program:

a. Encourage innovative R&D efforts for DOD systems and equipment which complement and broaden the spectrum of DOD concepts.

b. Develop technical competence in two or more contractors to encourage competitive responses to DOD procurement efforts.

c. Contribute to the economic stability of the private sector by allowing companies sufficient technical latitude to develop a wide variety of products for a broad base of DOD customers.

DOD currently has two special thrusts for the IR&D program: increasing industry-university interactions and emphasis on weapon system support and readiness issues. These thrusts are described below.

a. Industry-University Interactions - The goal is to encourage increased interactions between DOD contractors and universities, both to strengthen the technical

manpower base from which industry draws, and to increase the rate of technology transition from the academic community to industry. Desired interactions are those that strengthen research capabilities of the universities in science and engineering, contribute to development of high quality science and engineering graduates, and promote transition of research results into new applications.

b. Weapon System Support and Readiness - Improvements in support and readiness are major DOD objectives in the weapon system and logistic support technology areas. Technical innovation is essential in order to improve the readiness of our systems. Increased emphasis is required on technology areas which increase mission reliability, reduce dependence on support equipment, spares, and repair facilities, and reduce the need for highly-skilled personnel. Since these objectives are being integrated into DOD programs, it also is important that these objectives be reflected in defense contractor IR&D programs.

DOD manages the IR&D program in accordance with the requirements of Public Law 91-441, Section 203(a). This law authorizes DOD to pay IR&D and bid and proposal (B&P) costs only if the work for which payment is

being made is relevant to the functions or operations of DOD and if specific conditions (discussed below) are met for companies that recover more than $2.0 million in IR&D and B&P costs per year from the DOD. Public Law 96-342, Section 208, raised this threshold to $4.0 million and delegated authority to the DOD to increase this threshold every third year consistent with economic criteria. The next paragraph describes DOD activities which meet the specific conditions of Public Law 91-441, Section 203(a), as amended by Public Law 96-342, Section 208.

a. DOD currently negotiates advance agreements establishing a dollar ceiling on IR&D and B&P costs with all companies which, during their preceding fiscal year, received more than $4.4 million of IR&D and B&P payments from DOD. These ceilings are either negotiated directly with each such company or with those product divisions within a company which contract directly with DOD and which received more than $550,000 of IR&D and B&P payments from DOD. The IR&D ceiling is based on a contractor-submitted technical plan which DOD evaluates prior to or during the fiscal year of the advance agreement. DOD's allocable share of a company's IR&D and B&P costs can be no larger than the dollar value of IR&D and B&P efforts which have a potential relationship to a military operation or function.

b. For companies which during the preceding fiscal year received less than $4.4 million of of IR&D and B&P payments from the DOD, the IR&D and B&P ceilings are set by formula (Federal Acquisition Regulation 31-205.18). While the company does not have to submit a detailed technical plan to DOD for evaluation, it must submit a summary of the individual IR&D projects to the Administrative Contracting Officer responsible for determining the overhead rate for the company. Again, DOD's allocable share of a company's IR&D and B&P costs can be no larger than the dollar value of IR&D and B&P efforts which have a potential relationship to a military operation or function.

The growth of IR&D expenditures by contractors is shown below. Also, the percentage of these IR&D costs allocable to DOD has increased, due primarily to the growth in the DOD budget and the concurrent downturn in commercial sector sales.

IR&D COSTS
(Millions of Dollars)

Fiscal Year	1980	1981	1982	1983
Contractor-Incurred Costs	2373	2746	3654	3930
DOD Share	745	936	1193	1441

In order to focus IR&D Programs to meet DOD requirements, DOD interacts in several ways with contractors on technology base requirements:

a. Requirements information is transmitted to contractors through the technical comments made by individual evaluators during the annual review of contractor-submitted IR&D technical plans. Requirements information also is transmitted during formal and informal IR&D on-site reviews of the individual contractor programs.

b. Contractors discuss future requirements with the technology area focal points identified in the requirements documents issued by each Service. These documents are available to both current and potential contractors through each Service's Information for Industry Offices.

c. Most Service laboratories brief industry representatives annually on future requirements.

The following actions are recommended to improve DOD-contractor interactions on technology base requirements:

a. All DOD and Service R&D organizations should update their requirements documents and lists of technology area focal points on an annual basis.

57-279 O - 87 - 44

b. All DOD and Service R&D organizations should brief industry annually on future technology requirements.

c. All Service R&D organizations should continue to emphasize technical interaction with IR&D programs, including participation on both IR&D technical plan evaluations and on-site reviews. Industry IR&D planning will be influenced as companies gain further insight into DOD requirements. Likewise DOD planning will be influenced by the improved communications and understanding of technology emerging from industry.

E. SMALL BUSINESS INNOVATIVE DEVELOPMENT (SBIR) PROGRAM

On July 22, 1982, the President signed the "Small Business Innovation Development Act of 1982" (P.L. 97-219). This law was designed to give small high technology firms a greater share of Federal research and development contract awards. It became effective on October 1, 1982.

The Act mandated that all Federal agencies establish an SBIR program if their FY 1982 extramural budgets for research and development exceed a threshold figure of $100 million. (There are twelve government agencies meeting this requirement.) Beginning in FY 1983, DOD had to make available the following percentages of its extramural R&D budget for this program:

Fiscal Year	1983	1984	1985	1986	1987	1988
Percentage	0.1	0.3	0.5	1.0	1.25	1.26
Estimated Amount (Millions of dollars)	16.7	44.0	79.0	160.0	204.0	262.0
Actual Award (Millions of dollars)	20.6	44.6	--	--	--	--

Objectives of the DOD SBIR Program include stimulating technological innovation in the private sector, strengthening the role of small business in meeting DOD research and development needs, fostering and encouraging participation by minority and disadvantaged persons in technological innovation, and increasing the commercial application of DOD-supported research or research and development results.

The SBIR Program consists of three distinct phases. Under Phase I, DOD components make awards to small businesses, typically of one-half to one man-year effort over a period generally not to exceed six months, subject to negotiation. Phase I is to determine the scientific or technical merit and feasibility of ideas or concepts submitted in response to SBIR topics. The topics are published annually in a competitive solicitation document to which small businesses respond with proposals.

All DOD topics address specific R&D needs to improve our defense posture. Awards concentrate on that research or research and development that significantly contributes to proving the scientific or

technical feasibility of the proposed effort, the successful completion of which is a prerequisite for further DOD support in Phase II.

Phase II awards are not based on a solicitation but are made to firms on the basis of results from the Phase I effort and on the scientific and technical merit of the Phase II proposal. Special consideration is given to those proposals which identify a follow-on Phase III funding commitment from non-Federal sources.

Phase II awards typically cover 2 to 5 man-years of effort over a period generally not to exceed 24 months, subject to negotiation. The number of Phase II awards depends on the success rate of Phase I contracts and on the availability of funds. Phase II is the principal research or research and development effort, and requires a more comprehensive proposal outlining the effort in detail.

Phase III is expected to involve private-sector investment and support for any necessary development that will bring an innovation to the marketplace. Under Phase III, DOD may award non-SBIR-funded follow-on contracts for products or processes meeting the mission needs of DOD.

The legislation for this act was modeled after the Defense Small Business Advanced Technology (DESAT) Program instituted by DOD in FY 1982. In Phase I of DESAT, 100 contract awards of approximately $50,000 each were made from 1103 proposals received. From the 100 Phase

I awards, 33 Phase II awards worth $4.7 million were made. The DESAT awards are counted against the mandate of the SBIR Act for the fiscal year in which the awards are made. The DESAT program will be phased out with the completion of the current Phase II contracts.

FY 1983 SBIR Program

For the FY 1983 SBIR Phase I contract program, the three Services and the Defense agencies selected more than 300 research and development topics from a description of needs which were included in the DOD SBIR solicitation brochure. This solicitation had a closing date of May 31, 1983. The following is a breakout of the proposals received and those for which Phase I contracts were awarded:

	Number of Topics	Proposals Received	Phase I Awards
Army	182	1121	96
Navy	131	944	67
AF	75	496	100
DARPA	8	128	12
DNA	10	88	8
Totals	406	2777	283

FY 1984 SBIR Program

The solicitation brochure for the FY 1984 DOD SBIR Phase I Contract Program was mailed out on October 17, 1983 (approximately 42,000 copies were distributed) with a closing date of January 12, 1984.

Resulting proposals were evaluated by the scientists and engineers in the Services and Defense agencies who generated the topic descriptions. The announcements of proposals selected for contract negotiations were made by the Secretary of Defense on August 1, 1984. A breakout follows:

	Number of Topics	No. of Proposals Received	No. Selected for Phase I Negotiations
Army	111	761	78
Navy	147	847	99
Air Force	283	1212	164
DARPA	17	107	15
DNA	8	80	12
Totals	566	3007	368

Of the 283 FY 1983 Phase I contract awards, the following Phase II contract awards are anticipated:

Army - 30 to 35

Navy - 37

Air Force - 50

DARPA and DNA - 8

Funding of the two year Phase II contracts will be by yearly increments.

FY 1985 Program

The SBIR solicitation for Phase I proposals for FY 1985 began with the selection of the research and development topics by the Services and Defense agencies. This process was completed in August 1984. The topics were consolidated into a single DOD solicitation brochure and distributed on 1 October 1984. The Army has 111 topics, Navy 138, Air Force 218, DARPA 17, and DNA 7. Potential offerors had until 31 January 1985 to submit proposals. For FY 1985, the Strategic Defense Initiative Organization will have 18 topic descriptions in a supplemental DOD solicitation released on 1 January 1985, with a closing date of 31 March 1985.

The Small Business Administration (SBA) is charged by P.L. 97-219 with maintaining a source file of all small firms wishing to be notified of the availability of SBIR solicitations from all twelve agencies of the government. DOD makes an automatic mailing of its SBIR solicitations to all of the firms on SBA's mailing lists. The FY 1985 solicitation has been mailed to 21,959 small R&D high-tech firms.

F. RECOMMENDATIONS AND FUTURE PLANS

Based on the discussion in Section A, AF laboratories were asked for policy changes that might substantially reduce the contracting workload on contracts less than $300,000 per year. The responses were varied, but there was general agreement that several actions might be taken to reduce the contracting workload. Some actions would require only Service or DOD regulation changes.

Examples of procedural changes cited which would simplify laboratory contracting for small contracts include:

(1) Eliminating cost schedule reports.

(2) Eliminating the Small Business subcontract requirement.

(3) Relaxing of time accounting requirements.

Three recommendations for major changes (requiring FAR or law changes) were received as follows:

1) Set up an SBIR-like, set aside program for universities to which they can respond with simplified proposals. A portion of the technology base would be reserved for this program. This approach would resolve only a portion of the problem, as the university community represents only a part of the science and technology programs. Also the

university community generally competes well in the research program but does not go beyond applied research into development.

2) Revise PL 98-72 and the Competition in Contracting Act, to remove synopsis requirements for small contracts and consider other restrictions which may be eliminated to encourage more participation in laboratory contract programs without increasing paper work.

3) Arrange for a special contract/procurement instrument (in some ways similar to a grant for basic research) for the laboratory community which would allow simplified proposals, contracting procedures, and administration for procurements with obligations of less than $300,000 per year. This would require legislation to allow simplified procedures and a relaxation of data requirements for small contracts. A simple procedure is envisioned that could be applicable to small business, the university community, and those researchers in major industrial laboratories working on new technologies. The proposed instrument might also take the form of a cooperative agreement whereby DOD and the contractor/grantee would share costs, one buying equipment and the other providing workspace and salaries. It would appear that considerable savings in

time and effort could be made by allowing laboratory extramural programs more flexibility in 6.1 and 6.2 procurements with obligations of less than $300,000 per year. Furthermore, it is likely that both government S&E personnel and the proposer community would welcome a dialogue on the subject.

4) Authorize the use of small purchase procedures and forms for small R&D contracts or permit the use of purchase orders.

5) Give consideration to the use of Basic Ordering Agreements with task orders as an acceptable type of contract for certain R&D and R&D service requirements.

In summary, this chapter started with a discussion of laboratory programs in science and technology, and ways in which they differ from systems acquisition programs. Short sections on industry participation in IR&D and SBIR were included to give examples of the breadth of current programs which support the national technology base. The conclusions encompass a possible new approach to simplifying the technical interaction between government laboratories, industry, and universities. As a result of this study, DOD will propose draft legislation which would simplify contracting for small R&D contracts.

CHAPTER V

TECHNOLOGY BASE ACTIVITIES OF OUR ALLIES

A. OBJECTIVES

The United States and its allies are relying on superior technology to meet the threat posed by their adversaries. In sheer quantities of military resources, our adversaries have us outnumbered. We must, therefore, balance this numerical threat in part by relying upon qualitatively superior weapons systems to maintain our collective strength. By equipping our forces with weapons systems that are technologically superior to those of our potential adversaries, we use fewer people and increase the leverage of our defense dollars. To counter the threat in any other manner would require substantial increases in the military budgets of the U.S. and its allies.

So far, we have managed to stay ahead of the Soviets in most deployed technologies, but in some areas our lead is fragile and, in others, we are clearly behind. Several factors contribute to the loss of, or reduction in, our technological lead. One is the length of time required for weapons systems development. The period from beginning of development to actual deployment can be ten to twenty years, and a deployed life of twenty additional years is not unusual. The fruits of this long-term investment are seriously jeopardized if our potential adversaries obtain a system's technology early in its development or

test cycle. In recent years, DOD has proposed substantial increases in its RDT&E budget for the purpose of deploying technology in weapons systems more quickly than we have in the past. The Congress has been very supportive of DOD's efforts in this regard.

The pluralistic makeup of our allies represents a second area of vulnerability. Joint allied use of advanced technology in weapons systems is subject to multilateral negotiations and mutual agreement among partners. As a result, progress in modernizing our forces is sometimes agonizingly slow, and this pace affords the Soviets time to narrow our technological lead.

The changing relationship between civilian and military technologies also makes our lead vulnerable. Thirty years ago, military technology was far ahead of that in the private sector; sophisticated military electronics had no civilian counterpart. Today the situation is very different. We increasingly find that military systems incorporate technology which already is in the marketplace. The microelectronics revolution, for example, placed advanced computers in the hands of the public long before the military equivalents became part of weapons systems. This situation is of great benefit to the public, but makes it much more difficult to protect our technological lead in important technologies which are available commercially.

Finally, and perhaps most importantly, the massive Soviet effort to acquire Western military technology by both overt and covert means threatens our technological lead.

To maintain our technological lead, we must carefully steer a course between two extremes. On the one hand, we must not restrict technology exchange to such an extent that we actually slow the pace of allied technological development. On the other hand, we cannot be cavalier in the face of Soviet success in acquiring important technology. Like many difficult real-world problems, control of unfavorable technology transfer is within the realm of the possible; it requires a pragmatic approach that balances the competing policy considerations and also achieves a favorable benefit-cost ratio.

Our technological lead can be increased or maintained in two ways--by moving the West further ahead and by holding the Soviets back. Recognizing this, the United States has adopted an approach of promoting technology exchange and development with our allies, while at the same time restricting technology transfer to potential adversaries. These activities complement each other; neither can succeed alone.

With regard to export control, the United States has undertaken initiatives designed to restrict the flow of militarily critical technology to our potential adversaries. These initiatives constitute a realistic course of action. They recognize that it is impossible to

prevent all undesirable technology transfer. Some transfer occurs and will continue to occur illegally. An open society, which is absolutely essential to our continued scientific and technological progress, creates some targets of opportunity for the Soviets that we can never fully protect.

The objective of export controls, then, is delay, not prevention. High technology is a perishable item and, during its useful life, we want to make the know-how difficult for the Soviets to obtain. If they do succeed, we want to make the effort as costly as possible. Let the Soviets expend their own resources to acquire high technology rather than get it from the United States and its allies at a fraction of what it cost us to research it, develop it, engineer it, manufacture it, and control its quality. We will be better able to maintain our advantage if the Soviet economy has to bear the full economic costs of technological innovations.

It is also important to recognize that the United States, with few exceptions, does not have a monopoly on technology. Therefore, if controls are to be effective, they must be multinational. Otherwise, American industry would find itself, in effect, excluded from marketplaces that are open to its foreign competitors.

Finally, our export control efforts acknowledge that the United States, as a practical matter, cannot police all activity of this

kind. Consequently, the government's limited resources are concentrated on those areas offering the highest potential payoff.

B. CURRENT MECHANISMS FOR EXCHANGE, COOPERATION, AND COLLABORATION

DOD is working closely with U.S. allies to identify technological opportunities which make the best use of our combined resources and achieve the objective of maintaining superior technology for future weapons systems. In addition to informal approaches, there are several formal mechanisms which promote the objective. Among the latter are The Technical Cooperation Program, NATO's Defense Research Group, the Services' basic research offices in London and Tokyo, and, more recently, the technology assessment teams established to explore the transfer of military technology from Japan to the United States.

The Technical Cooperation Program had its origins in a Declaration of Common Purpose made in 1957 by the President of the United States and the Prime Minister of Great Britain. The statement recognized that the concept of national self sufficiency was out of date, that the countries of the free world are interdependent, and that progress and safety could only be found in genuine partnership by combining resources and sharing tasks in many fields. Since then, Canada, Australia, and New Zealand have joined the program. A number of subgroups were established in appropriate fields of defense research and development. Briefly, the purpose of the subgroups is to formulate proposals designed to obtain

maximum cooperation and optimum employment of resources for research and development, and to ensure as complete an interchange of information as possible among the five countries in designated areas of the defense research and development technology base. Among the designated areas are chemical defense, undersea warfare, aeronautics technology, infrared and optical warfare, communications technology, behavioral sciences, and conventional weapons technology.

NATO has established the Defense Research Group. The Group consists of senior national representatives capable of speaking with authority on the application of science and technology to military problems and resulting national research programs. The Group has several objectives: to exchange information on new research and technology which might lead to future equipment; to review the possible military consequences of advances in the fields of science and technology; to identify suitable areas or individual proposals for bilateral or multilateral cooperation in defense research; to implement this research; and to avoid duplication of effort. Technical panels and research study groups have been established in physics and electronics, optics and infrared, defense applications of operations research, defense applications of biomedical research, electronic warfare concepts and technology, long-range research related to air defense, and long-term scientific studies (not technology specific). In addition, a special study group has been established in concealment, camouflage, and deception.

Recently, the NATO efforts have concentrated on emerging technologies in four mission areas: (1) defense against first echelon attack; (2) attack of follow-on forces; (3) counter-air; and (4) C^3I and counter-C^3I. The goal is to make visible and expeditious progress in cooperative efforts to field effective systems that would otherwise not be widely deployed--in other words, to concentrate on the utilization of more proven technologies in deployed systems.

More recently and of more interest to this report, there has been increasing attention to technology emerging from basic and applied research efforts. The increasing interest in being able to identify, at an early stage, the technologies which may be important to future defense systems is fueled as much by economic considerations as by security. Some of the questions which are being addressed are how to identify high-leverage technologies, whether an identification procedure could be used for an investment strategy, and what degree of protection or control should be provided.

The Services maintain research offices in the U.K. and Japan to meet their needs in matters relating to science and technology overseas. The primary responsibility of those offices is to keep informed on scientific and technological developments in Europe, the Middle East, and the Far East. The offices also establish contacts between American and foreign scientists in important technical areas and provide liaison between the U.S. and foreign scientific communities.

During the past two years, DOD has worked with the Japanese to implement the Nakasone Cabinet's January 1983 policy statement allowing the transfer of certain military-related technology to the U.S. DOD hopes to establish a long term program of cooperative efforts and transfer of technology. Our initial efforts have been toward assessing the status of Japanese technology in the area of fiber optics, electro-optics, infrared and millimeter wave components, and sensors. This was accomplished by a team of experts who visited Japan in 1984. The teams' assessment, conclusions, and recommendations are being evaluated in DOD.

C. SUMMARY

In Europe, both the need and the opportunity exist to increase cooperation with our allies. European economic conditions are not as favorable as those in the United States and, as a result, many countries are cutting back on research. European researchers are some of the best trained in the world, usually have excellent equipment, and, in certain areas have unique data gathering capabilities.

The situation with regard to Japan is somewhat different. The Japanese government, business managers, bankers, and researchers select their technological areas based on long term national industrial and economic needs. Although excellent basic research is conducted, the emphasis is definitely on the application of technology. This does not mean, however, that there are no opportunities for increased collaboration.

As described in this report, there are many joint programs, joint developments, joint experiments, and data and information sharing activities with our allies. Where appropriate, the cost of this effort is shared. Since the United States and its allies are relying on superior technology and the leverage it provides, it is essential that we reexamine the resources that the United States is applying to the technology base portion of DOD's RDT&E budget. Otherwise, future weapons systems will not have the leverage of superior technology and the United States would have to increase its defense expenditures in an effort to match adversaries tank for tank, plane for plane, man for man.

CHAPTER VI

CONCLUSIONS

DOD recognizes the importance of the nation's scientific establishment to our future security. This establishment, a combination of our universities, industry, and in-house laboratories, requires continued attention to ensure that it is sustained at a sufficient level, and is of sufficient quality, to maintain our technological lead over potential adversaries.

This report, prepared at the request of the Senate Committee on Armed Services, has addressed the DOD S&T program and has identified areas which need and are receiving special attention:

- Additional funding is needed to pursue defense science and technology programs required to sustain a U.S. technological lead. Two specific actions have been taken. Approximately 9 percent real growth has been requested in the FY 1986 budget. In addition, the Secretary of Defense has issued guidance for real growth in both the Basic Research and Exploratory Development Programs starting in FY87.

- A DOD-University Research Initiative to help revitalize university science infrastructure as a step toward maintaining the S&T base required for national security has been included in the FY86 budget. Particular attention will be given to potentially high payoff projects in emerging technologies, research instrumentation, graduate fellowships, and research assistantships.

In addition:

- Improvements in the quality of the scientists and engineers at in-house laboratories as well as universities are being sought. A new personnel management system for scientific and technical personnel in the Federal government is needed to improve management flexibility and the ability to attract, retain, and motivate a high quality scientific and technical workforce.

- Research instrumentation is needed to provide scientists and engineers with the tools required to perform quality work. FY 1986 will be the fourth year of a five year, $150 million program to upgrade instrumentation of universities performing defense-related research. In addition, DOD is assessing university facility needs to

perform defense-related research. The report on this assessment is in preparation and will be provided to the Congress when completed. During 1986, DOD will assess in-house laboratory research instrumentation and facility requirements. These needs will be reflected in future budget requests.

- Efficient interactions in the S&T Program among the in-house laboratories, universities, and industry are needed. DOD currently is reviewing potential changes to internal procedures in order better to accommodate the Federal Acquisition Regulations, PL 98-72, and the Competition in Contracting Act. If necessary, draft legislation will be proposed to facilitate these activities.

- S&T cooperation and collaboration with our allies, which engenders a larger common technology base and enhances mutual understanding of defense technologies is strong and should be strengthened if possible. Bilateral and multilateral agreements for jointly developing and sharing technology are being improved with particular emphasis on agreements with NATO, The Technical Cooperative Program countries, and Japan.

INTRODUCTION

A. RATIONALE

The Report of the House Armed Services Committee on the 1984 Department of Defense Authorization Act contained the following request: "Many of the university laboratories in which Department of Defense research programs are conducted are obsolete and in need of major modernization or replacement. The committee believes a study should be undertaken on the need to modernize university laboratories in the physical sciences, earth and ocean sciences, atmospheric sciences, engineering, computer sciences and other fields essential to our long-term national security. The survey should (1) document the laboratory needs of universities presently engaged in Department of Defense competitive research programs, (2) assess priorities by academic field, (3) provide estimates of costs to meet these needs, (4) provide specific recommendations appropriate to the Department of Defense and others designed to address the need, (5) state the consequences to our long-term national security."
This report is a response to that request.

The science and technology (S&T) base has, as its cornerstone, basic research which, in the U.S., tends to be concentrated at universities. Approximately two-thirds of basic research in science and engineering (S&E) is carried out in academia. There is a concomitant integration of basic research with graduate education. The nation reaps a double benefit from this model in that it concurrently generates both research results and future researchers. It is for this reason that the state of U. S. university laboratory facilities is so important to the nation's long-range economic and military competitiveness.

The evolution of science and technology tends to create a requirement for more sophisticated research facilities. Failure to keep pace with facilities' needs has a negative impact on researchers' creativity. This in turn limits the scope of scientific endeavor in the experimental disciplines. The consequences may include delays in the realization of new discoveries and a trend for faculty and graduate students to opt for theoretical studies rather than engage in experimental research with inadequate facilities. A further consequence is the difficulty of recruiting and retaining the most productive faculty in experimental disciplines.

The foregoing points work against university researchers undertaking experimental investigations. When researchers do so in spite of inadequate facilities, results of their endeavors can be compromised in a variety of ways. These include:

- Inadequate environmental control resulting in decreased quality of data
- Excessive down-time resulting in diminished productivity

- o Outmoded equipment leading to imprecision in acquired data
- o Crowded laboratory space resulting in diminished access to equipment for data gathering and maintenance purposes
- o Contrived experimental set-ups representing safety hazards

B. DEFINITIONS

The following definitions will be used throughout this report:

Laboratory Needs-Facilities and equipment which collectively constitute vehicles for the generation of experimental data and other information. It denotes more than a stand-alone instrument (e.g., spectrometer, tensile tester, etc.) that can be operated in general laboratory space typically found on a university campus, but excludes general purpose laboratory buildings. Examples include wind tunnels, high voltage accelerator labs, clean rooms, wave tanks, etc., especially those housed within existing older buildings. It may also include specially designed structures required to house laboratory instrumentation and experimental facilities.

Facilities-Laboratory structural environment including hardware required to maintain special conditions in laboratory space.

Equipment-Instrumentation and devices directly supportive of data acquisition and analysis.

C. RESEARCH DISCIPLINES AND THRUST AREAS

Selected research laboratory needs among universities active in Department of Defense (DOD) competitive research programs are addressed in this report for the following five disciplines and constituent thrust areas:

CHEMISTRY
- Laser Chemistry
- Polymeric Materials

ELECTRONICS
- Microelectronic Fabrication and Reliability
- System Robustness and Survivability

ENGINEERING
- Combustion
- Composite Structures
- Energetic Materials
- Fluid Mechanics and Acoustics
- Manufacturing, Design, and Reliability
- Soil Mechanics

MATERIALS
- Optical and Magnetic Materials
- Silicon and Compound Semiconductor Growth
- Structural Ceramics
- Structural Composites

PHYSICS
- Astrophysics
- Coherent Radiation Sources
- Directed Energy Devices
- Optical Communications and Spectroscopy

The foregoing disciplines do not represent the breadth of DOD research. In particular, biological and biomedical sciences are not included in anticipation of a comprehensive survey of laboratory needs by the National Institutes of Health. Computer resources not dedicated to experimental research facilities are also excluded on the basis that they are the object of considerable study and/or aggressive enhancement programs by the National Science Foundation and the Department of Energy.

D. INFORMATION ACQUISITION

Requisite information was initially assembled by research administrators in the three Service research offices (OXRs): the Office of Naval Research (ONR), Army Research Office (ARO), and the Air Force Office of Scientific Research (AFOSR) and in the Defense Advanced Research Projects Agency (DARPA). In particular, Division Directors in each organization representing the foregoing five research disciplines supplied data related to the sufficiency of research laboratory facilities. This information was analyzed for the purpose of developing laboratory needs representative of defense research priorities. Results are presented in Chapter IV in the form of prioritized laboratory needs (where they exist), estimated costs of desired enhancements, and assessments of the scientific/technological and national security implications of any laboratory needs identified.

Within the framework of the foregoing information acquisition plan, each of the three OXRs identified key R&D performers for the various research disciplines. These performers were then analyzed with reference to the indicated questions. Criteria used in determining the performers to be interrogated and/or analyzed for inclusion in the report involved level of basic (6.1) competitive research funding, evaluations by OXR research administrators, and, as appropriate, independent evaluations of graduate programs corresponding to the various disciplines. In many cases, the stated costs represent partial funding reflecting the tendency of universities to seek multiple sponsors for major laboratory improvements. While the method of data collection does not embody the statistical integrity of a rigorously implemented survey instrument, it is nonetheless thought to be suggestive of the dimensions of university laboratory needs of greatest importance to DOD. Further, the study differs from previous ones in that the cited laboratory needs reflect, in part, the judgment of research sponsors (DOD scientific officers) rather than exclusively the perceptions of research performers.

The primary DOD research performers encompassed by this report are, of course, only a subset of the total university R&D community. The extent to which their modernization and new facilities needs may be extrapolated to all universities performing research for DOD, or to the entire population of approximately 300 research universities in the U.S., is an open issue. Such extrapolations beg the question, however, as to appropriate means for assessing laboratory sufficiency from the DOD perspective. This is a complex question that is under constant scrutiny for each discipline and its constituent research areas. More generally, it is an issue which demands continued vigilance at the national level. Sustained deficiencies in any discipline/thrust area will inevitably cause the corresponding sector of the U.S. science and technology base to erode, thus blunting our competitive position in the national security and world economic arenas.

CHAPTER II
DOD SUPPORT FOR UNIVERSITY LABORATORIES

A. INTRODUCTION

This chapter deals with the role that universities play in sustaining and strengthening the U.S. science and technology base (Section A), the origins of DOD support of university laboratories in that role (Section B), DOD programs that support university science laboratories (Section C.1), and further steps that DOD has taken to upgrade these facilities (Section C.2). A new university research initiative for FY 86 (Section C.3) and coordination activities relevant to the upgrading of university research facilities are described (Section C.4).

Given the importance of university science laboratories to DOD, it is also true that maintaining adequate university research facilities is a national priority that has important economic as well as military significance. Thus, DOD should not and cannot solve the problem alone. Solutions must encompass all relevant government agencies, private industry, and, of course, the universities themselves. This chapter focuses, however, on the relationship between DOD and the university community.

American universities play an indispensable role in maintaining and strengthening the nation's science and technology base. Not only are universities the source of future scientists and engineers, but the research contributions of academia to society are vast as well. Since World War II, universities have performed most of the basic research that has produced the technological innovations on which much of our economy and national defense are based today. Universities contribute nearly three-quarters of the scholarly papers published in the most noted science and technology journals. In addition to generating the insight and knowledge upon which future technological innovation is based, university research provides the environment for the development of future scientists and engineers. The result is enrichment of the professional experience of faculty and graduate students involved in training our nation's technical manpower. Thus, support of university research produces multiple benefits of enormous value to society as a whole.

This report addresses selected needs of university laboratories involved in DOD sponsored research. As much as $2 billion has been estimated as the total sum needed to replace obsolete university research instrumentation. Laboratory facilities, including the instrumentation required to conduct research aimed at modernizing and expanding the U.S. technology base, are becoming increasingly expensive. Establishing and maintaining such facilities are very costly, especially those requiring advanced supercomputers, large particle accelerators, various types of analytical instrumentation, imaging devices, and automated design and manufacturing hardware. Nonetheless, such equipment is crucial for the conduct of research in important areas of science and engineering, and for educating students. DOD support for university research equipment is described in the following sections.

B. ORIGINS OF DOD SUPPORT FOR UNIVERSITY LABORATORIES

The DOD has recognized that technological superiority is essential to military superiority, and it has played an important role in maintaining the strength of the U.S. science and technology base. Since DOD was among the first federal agencies to recognize the essential role that the academic community plays in the maintenance of U.S. technological leadership, it has maintained a strong relationship with U.S. universities since before World War II.

Very little involvement of universities with military technology occurred during World War I, despite the existence of in-house Service laboratories since the 1890s and the earlier creation of the National Academy of Sciences, which was established as a war measure by President Lincoln in 1863. The sudden expansion of experimental and laboratory operations that characterized the outbreak of World War II greatly overburdened the Service laboratories. Many civilian scientists and engineers were added to the staffs of Aberdeen Proving Grounds, the Naval Research Laboratory, the Naval Ordinance Laboratory, Taylor Model Basin, Wright Field (Army Air Force), and Fort Monmouth (Signal Corps). Contracting funds were also greatly increased in the effort to catch up to an enemy that had scientific groups investigating improved weaponry since the early 1920s.

The Office of Scientific Research and Development (OSRD) was created, reporting directly to President Roosevelt, and receiving funds by direct appropriation from the Congress. These funds were placed in private and governmental laboratories. The National Research Council of the National Academy of Sciences had been created during World War I and was, by the time of World War II, well known to the military Services, which expanded their use of it. These arrangements formed a close coupling of the organized bodies of scientists and military leaders having a common appreciation of the importance of science and engineering to modern warfare. Major wartime expansion of facilities occurred at several universities. The major contributors included MIT, Harvard, Columbia, the University of Chicago, the University of California, the Johns Hopkins University, and the California Institute of Technology. Radar, acoustics, operations research, navigation, and atomic weapons were just a few of the areas in which notable contributions were made.

Emerging from the wartime era were two lasting methodologies for defense investment in university laboratory facilities. First, the institute concept became well established, wherein non-profit university affiliated laboratories conduct applied research, primarily under DOD support. Products of this era which make major contributions today are Lincoln Laboratories (MIT), the Johns Hopkins University Applied Physics Laboratory, the Applied Physics Laboratory of the University of Washington, the Applied Research Laboratories of the University of Texas, the Applied Research Laboratory of Pennsylvania State University, and the Marine Physical Laboratory, Scripps Institute of Oceanography, University of California, San Diego. Second, the National Security Act of 1947, and the amendment of 1948 which established the three military Departments and the Office of the Secretary of Defense, provided the framework that operates today for support of research at universities through the Army Research Office, the Office of Naval Research, the Air Force Office of

Scientific Research, and the Defense Advanced Research Projects Agency. This partnership has been substantial over the years; seventeen institutions of higher education are among the 595 contractors that received awards of 10 million dollars or more from DOD in FY 83.

C. PRESENT DOD SUPPORT FOR UNIVERSITY LABORATORIES

C.1 DIRECT FUNDING OF UNIVERSITY RESEARCH

U.S. universities are a major factor in current DOD activities affecting the U.S. technology base. Approximately half of all DOD basic research (6.1) funds are expended at universities ($405 million in contract dollars with research budgets totaling $840 million in FY 84), plus a smaller amount of applied research (6.2) funds (approximately $115 million in FY 84). During the past decade, DOD has made a major effort to reverse the effects of the relative neglect of university research that occurred during the Vietnam war. Figure II-1 shows the evolution of DOD funding for basic research (6.1) since 1962. The corresponding funding history for "exploratory development" (6.2), some of which equates to applied research, is shown in Figure II-2.

These figures show that funding in current dollars for both components of the technology base grew significantly during the late 1970s and early 1980s; nevertheless, neither has returned to 1965 levels of support in constant dollars. In fact, in real terms, the level of funding for exploratory development has been virtually stable for over a decade. In a memorandum to the Services dated August 9, 1984, Secretary Weinberger noted this situation and indicated that the Defense Guidance for the FY 1987-91 POM would request 8 percent annual real growth in both components of the technology base. DOD still takes that position.

University research has been a major component of the growth in DOD technology base activities during the past decade. Table II-1 shows DOD Basic Research (6.1) funds spent (or projected to be spent) at universities by the Army, Navy, Air Force, and the Defense Advanced Research Projects Agency (DARPA) for the years FY 74-86. During the period FY 75 to FY 84, DOD spending for 6.1 Basic Research at universities grew at a real annual rate of 9 percent--far higher than the annual growth of DOD Research (6.1) funds as a whole.

Table II-1 shows only the DOD Basic Research (6.1) funds going to universities. It includes only contracts exceeding $25,000, and does not reflect research grants. Thus total university funding is somewhat higher than indicated. A similar break-out of the university component of DOD Exploratory Development (6.2) funds is not available. To provide a basis for comparing 6.1 and 6.2 expenditures, in FY 83 a total of $102.3 million in DOD Exploratory Development (6.2) contracts went to universities while $360 million was provided for Research (6.1) contracts. An additional $50 million was awarded to universities in the form of 6.1 research grants. DOD funding for universities is not limited to Research and Exploratory Development. For example, DOD RDT&E (6.1 through 6.6) contracts over $25,000 going to educational institutions in FY 83 totaled $1113.6 million. Most of the $600 million in the higher categories (6.3, 6.4, 6.5, and 6.6) was for R&D in university affiliated off-campus laboratories and Federally Funded Research and Development Centers (FFRDCs), or for vocational and technical training, and tuition fees.

DOD sponsors research and development at universities to ensure the progress in fundamental knowledge that is necessary, in the long run, to maintain U.S. technological superiority. The resulting university research programs also serve to benefit universities in a variety of ways. By providing opportunities to perform basic research at the forefront of science and engineering, research programs at universities help to create an environment that can attract and retain faculty and students. Past studies suggest that, on average, $1 million of funding for research provides full or partial financial support for 10-15 graduate students. Using this measure, DOD provided financial assistance for over 4000 graduate students through its university research programs in FY 84. In addition, as will be noted below, DOD-related research programs also have significant effects on laboratory instrumentation.

C.2 INSTRUMENTATION PROGRAM

Instrumentation is essential to modern research. Modern instruments with qualitatively superior capabilities for analysis and measurement often open new fields of scientific inquiry. In some scientific areas, access to the most advanced scientific instrumentation determines in large measure the extent to which scientists can work at the cutting edge of their field.

The Department of Defense, in concert with the scientific and university community, state and other federal agencies, and the Congress, perceived that the condition of research instrumentation in U.S. universities declined significantly during the 1970s. The Association of American Universities (AAU), in a report to the National Science Foundation (NSF) in June 1980 (see Chapter III), concluded that the equipment being used in the top ranked universities has a median age twice that of the instrumentation available to leading industrial research laboratories, an additional factor in the attraction of potential faculty to industry.

The instrumentation problem has been growing for more than a decade. It reflects both economic factors and funding patterns:

- The cost of equipment has risen much faster than inflation.
- The system of one to three year contracts in the $50,000 to $100,000 per year range with individual investigators is not conducive to obtaining equipment that costs more than $50,000.
- Rapid technological advances are rendering research equipment obsolete at an ever increasing rate.

In response to the foregoing situation, DOD has encouraged researchers to include more of their equipment needs in proposals and emphasized that DOD does not set arbitrary limits on the amount of money that may be requested for instrumentation. This approach has been helpful for equipment needs in the $50,000 range or less. However, new money was clearly needed for some of the more expensive items required to modernize university laboratories. These funds were provided in FY 83 through the DOD-University Research Instrumentation Program (URIP), which received Congressional approbation.

URIP provides $150 million over five years for university research equipment. Each of the three Services is programmed to spend $10 million per year. So far, $90 million has been spent on 652 awards going to 152 institutions in 47 states and Washington, D.C., Guam, and Puerto Rico. While URIP is having a major impact on the equipment needs of researchers doing work of interest to DOD, it cannot solve the whole university instrumentation problem. In the first year of URIP, DOD received 2,500 proposals representing requests for $646 million worth of equipment. While some of these requests were for equipment to support research in areas not usually funded by DOD, this response is a significant and impressive measure of the needs of the universities.

URIP is the most visible, but not the sole, DOD response to the university instrumentation problem. As noted previously, each of the Services and DARPA have encouraged current and prospective contractors to make their equipment needs known, in order that many of the less expensive items could be purchased as an integral part of research program funding:

- Approximately 10 percent of Army, Navy, and Air Force research contract funding is applied to equipment purchases, most of it well under $50,000. Grants under the URIP program provide an additional comparable dollar amount for equipment costing more than $50,000.

- The portion of the Army Research Office (ARO) contract program devoted to instrument purchases has increased steadily over the past decade; in FY 85, such purchases will represent about $6 million of the ARO contract research program.

- University-related equipment purchases associated with the Contract Research Program of the Office of Naval Research (ONR) increased from $11.2 million in 1979 to $16.6 million in 1984.

- Between 1975 and 1985, vested equipment funding by the Air Force Office of Scientific Research (AFOSR), during the usual course of its sponsored research program, increased from $2 million to $8 million.

- Although DARPA does not participate in the URIP program, 10 to 20 percent of its university program funds have been utilized for equipment. In 1981, DARPA began a modernization program focused on obsolete equipment and the need for greater computational power. From 1981 to 1984, equipment purchases by universities using DARPA funds increased from $6.7 million to $16.8 million.

In certain cases where the equipment for major research efforts has been especially costly, provisions have been made for extraordinary purchases. Examples include the purchase of large main frame computers, semiconductor processing lines, molecular beam epitaxy and analysis chambers, and ARPANET computational and communication facilities by DARPA, and an ongoing ONR program to refurbish selected research vessels.

In FY 84, in addition to the $30 million per year of special URIP purchases, the three Services and DARPA purchased over $45 million worth of research instruments and equipment for universities in connection with their research contracting activities.

C.3 UNIVERSITY RESEARCH INITIATIVE

In FY 86, DOD plans to establish new research program elements that will be focused exclusively on the DOD/university relationship. Total proposed funding for the new program elements is $25 million in FY 86 and $50 million in FY 87. Significant additional growth is expected after FY 87. Each of the Services and DARPA will implement programs within these program elements to meet the priorities of their own relationships with the academic community. Although the specific proportions will vary from Service to Service, graduate fellowships, support for young investigators, purchase of research instrumentation, support of special research programs, and programs to improve the interactions between DOD laboratory and university researchers, will be part of the total DOD package.

C.4 COORDINATION ACTIVITIES

DOD has long recognized that the academic community is an invaluable source of expert advice. The Department draws on science and engineering faculty as individual consultants and as members of DOD advisory committees. To insure more effective communication with the academic community, DOD established the DOD/University Forum in December 1983. During its first year, the Forum has provided a mechanism for dialogue between DOD and the academic community on policy and other issues of mutual interest. One significant outcome of its activities during the past year was the establishment of a new DOD policy on the transfer of scientific information. It establishes an appropriate balance between the conflicting imperatives of national security and open scientific communications. The Forum Working Group on Science and Engineering Education addressed many issues, including that of research instrumentation.

CHAPTER III

PREVIOUS STUDIES

More than a dozen studies of university laboratory facilities have been prepared since the late 1960s. For a comprehensive listing and summary of such studies prepared by Linda S. Wilson of the University of Illinois at Urbana-Champaign, see the Appendix. Many of these studies have concluded that a problem exists with respect to inadequate and deteriorating university laboratory research facilities. Some of the studies are qualitative and generally recommend programs for the support of facilities renewal. Others are quantitative and are based on surveys of the conditions of facilities, with projections of the amount and cost of construction and renovation required to meet future needs. The basic conclusion drawn is that renewal and replacement of facilities are an important element in assuring a national technology base. Some of the more relevant studies for the purposes of this report are discussed below. An analysis of some of their findings in comparison to the present study is given in Chapter V.

-- A report to the National Science Foundation (NSF) by the Association of American Universities (AAU) in June, 1980, was devoted to "The Scientific Instrumentation Needs of Research Universities." Numerical data for the study were gathered from 14 universities and four commercial laboratories. The report found that the median age of university equipment was twice that of the commercial laboratories' instrumentation. Concluding that "the quality of research instrumentation in major university laboratories" has seriously eroded, the AAU report recommended that:

> "Federal policy for the support of research instrumentation should provide for a basic three-part funding strategy:
>
> - o Strengthen instrumentation funding in the project system.
> - o Expand special instrumentation programs.
> - o Create in the National Science Foundation a new, supplemental formula grant program to provide needed flexibility to meet diverse institutional needs."

-- A 1981 study prepared for the Committee on Science and Research of the AAU, entitled "The Nation's Deteriorating University Research Facilities," was based on a survey of recent expenditures and projected needs of fifteen major U.S. universities in six disciplines. The principal findings of the study were:

- o A substantial backlog of research facilities and equipment needs was accumulating.
- o During the 1978-81 period, for the six fields surveyed, the fifteen universities spent $400 million for facilities and major equipment. In the next three years (1982-84),

these universities expected to spend almost twice as much ($765 million), just to produce the necessary research facilities and special research equipment for current faculty only.

- o New construction to replace outmoded facilities accounted for almost 60 percent of total projected funding requirements across all fields.

- o In addition, substantial needs for major research equipment were identified in all six fields.

Table III-1 shows the expenditures and projected needs for those disciplines included in the present report. Projected needs for both facilities and equipment were far larger (by factors ranging from three to almost ten) than actual expenditures for an equivalent period immediately preceding the report. The extent to which these differences represented realistic assessments of the pent-up facilities demand, and/or an effort on the part of survey respondents to "make a statement," is open to question.

Among the recommendations of the AAU study was:

- o Provided that a review by key government agencies corroborated the assessment of the survey, the "Department of Defense, Department of Energy, the National Aeronautics and Space Administration, the Department of Health and Human Services, and the Department of Agriculture should establish research instrumentation and facilities rehabilitation programs targeted on the fields of science and engineering of primary significance to their missions."

-- In 1982, Flad & Associates, a Wisconsin architectural and planning firm, published their "Capital Spending Study of Research and Development Laboratories." Since the study focused exclusively on the spending plans of private industrial firms, it provides a useful basis for comparison with the plans of universities dealt with in the AAU studies described above.

The Flad study was based on a survey of some 5800 directors of industrial research laboratories. About twelve percent of them responded with detailed, confidential estimates of planned spending for plant and equipment in the ensuing three years (1983-85). The firms surveyed were considered more representative of large research laboratories (25-100 staff) than smaller laboratories (less than 25).

Among the major findings of the Flad study were:

- o Estimated spending on research and development plant for 1983-85 by responding firms was $1.4 billion.

- o Estimated spending on research and development equipment for 1983-85 was $1.2 billion.

- o Nearly 40 percent of the laboratories of responding firms were built less than ten years before the survey; of these, 50 percent had undergone additions or renovations subsequent to initial construction.

Table III-1

Actual and Projected Expenditures for Research Facilities
(new construction/renovation) and Special Research Equipment
for 15 Major Research Universities
(thousands of dollars)

	FACILITIES			SPECIAL RESEARCH EQUIPMENT

Source: "The Nation's Deteriorating University Research Facilities",
Association of American Universities, 1981

For the purposes of this report, the Flad study has some interesting implications. If the study's findings are extrapolated onto the entire sample, total national private industry projected capital spending for research and development would be about $20 billion for 1983-85 (about $11 billion for plant and about $9.2 billion for equipment). This compares with estimates of $1 billion for total average annual planned investments in university science and education facilities. For industrial laboratories whose annual research and development budgets were in the range of 1 to 15 million dollars (45 percent of the responding firms), the expenditure planned for was about 13 percent of their annual operating budget each year for the three years beginning in 1983. The ratio of planned expenditures for equipment and plant by private industry was about the same (unity) as that shown for universities in Chapter IV below.

-- The NSF published a study of "Academic Research Equipment in the Physical and Computer Sciences and Engineering" in December 1984. This study surveyed 43 universities; respondents exhibited serious concern about the adequacy of their current stock of research equipment. Among the findings of the study were:

- o About half of the department heads in physical and computer sciences and engineering characterized research instrumentation available to untenured and tenured faculty as "insufficient."
- o 90 percent of the department heads surveyed reported that, as a result of lack of needed equipment, their research personnel could not conduct critical experiments in important subject areas.
- o The top priority need was to upgrade and expand research equipment in the $10,000 to $1,000,000 range.
- o The estimated original purchase cost of the entire 1982 stock of all $10,000 to $1,000,000 academic research equipment that had been accumulated in the fields surveyed was about $1 billion.
- o Only 16 percent of those systems were classified as state-of-the-art. Of the equipment that was not in the state-of-the-art category, over half was in less than excellent condition; about half of such equipment was the most advanced to which researchers had access.

In addition to the studies and data surveyed above, the NSF has released a variety of data that are of special interest for this report. Table III-2 gives seven-year trend data on capital expenditures at all U.S. universities for both research and instructional purposes. Unfortunately, there does not appear to be any systematic way of extracting purely research facility expenditures from these figures. The two research categories cited correspond roughly to the five disciplines addressed in this report.

TABLE III-2

Research and Instructional Capital Expenditures
at Colleges and Universities*

* 1978 Data not available.

Research equipment expenditures for U.S. colleges and universities are summarized in Table III-3 for 1982 and 1983. The data were obtained from 85 percent of U.S. universities in response to an NSF questionnaire concerning non-capitalized equipment expenditures. Engineering equipment purchases averaged approximately $70 million for the two year period. The category compares roughly to the combined engineering, electronics, and materials categories of this report.

Table III-4 lists 1982 estimated research equipment expenditures for 157 of the largest research universities. These 157 institutions collectively accounted for 95 percent of all nonmedical, non-FFRDC R&D expenditures reported to NSF for FY 1980 by all U.S. colleges and universities. Thus, although the survey represented only a small fraction of the nation's approximately 3,000 post-secondary institutions, it encompassed most institutions with significant capabilities for the kinds of advanced research that require instrumentation in the $10,000+ range. The quoted figures are somewhat higher than those in Table III-3, since they include capitalized equipment, whereas the data of Table III-3 do not. As in Table III-3, the engineering category compares roughly to the combined engineering, electronics, and materials categories of this report.

Acquisition and replacement costs as of 1982 for research equipment in the physical sciences and engineering are given in Table III-5. The total replacement value in 1982 dollars for both fields exceeded $1 billion. It is interesting to note that equipment maintenance in both the physical sciences and engineering represented 5 percent of replacement costs.

CHAPTER IV

SELECTIVE UNIVERSITY LABORATORY MODERNIZATION

A. INTRODUCTION

This chapter addresses selected laboratory needs, i.e. facilities and related equipment, for a segment of the research university community representing key performers of DOD research for the disciplines and thrust areas enumerated in Chapter I. These needs, stratified by discipline and priority in Table IV-1, reflect the judgment of university research performers and, in certain cases, of administrators in the Service research offices (OXRs) and the Defense Advanced Research Projects Agency (DARPA). It should be emphasized that the cost figures in Table IV-1 are estimates of university laboratory upgrade and modernization initiatives designed to bring university laboratories closer to sufficiency from the DOD perspective. As previously indicated, they represent in many cases only partial funding of the facilities in question through multiple sponsor arrangements. They are not intended to encompass laboratory needs of the entire university research community. The latter issue has been addressed in the various studies cited in Chapter III. Facilities costs vary among and within disciplines, reflecting special requirements for the various thrust areas. They encompass both floor space requirements and laboratory accessories not falling within the instrumentation category. Thus, not all expenditures classified as "facilities" represent requirements for new or renovated buildings. The stated new floor space requirements are expressed in "gross" (as opposed to "net") square feet at $\$120/ft^2$. Laboratory renovation costs are calculated at $\$90/ft^2$.

The allocation of laboratory needs among the five disciplines required the exercise of judgment as to the appropriate division between (a) the parent, pure science fields of Physics and Chemistry, and (b) the applications-focused areas of Electronics, Engineering, and Materials. Ultimately, such decisions are to an extent arbitrary. Further, there are clearly a great number of ways to stratify facilities and equipment needs in terms of disciplines and thrust areas. The scheme presented in this report is thus only one of many possible approaches.

Priority 1 facilities needs for the five subject disciplines, pro-rated over a five-year expenditure period, are $32 million per year. The expenditure level is equivalent to the URIP annual allocation of $30 million. It is also of interest to note that priority 1 equipment requirements are $31 million per year, i.e., almost identical to the annual expenditure rate of the five-year $150 million URIP initiative. Unquestionably, some portion of the $155 million Priority 1 equipment needs cited in this report will be addressed during the final two years ($60 million) of the URIP program.

Table IV-1. Summary of selected laboratory needs of major university performers of defense research.

Discipline	Priority	Building Requirements (gross ft^2)	Cost ($ thousands)* Facilities	Equipment	Total Costs
Chemistry	1	35,000	5,000	14,000	19,000
	2	412,000	44,700	33,400	78,100
Subtotals		447,000	49,700	47,400	97,100

	2	131,000	25,700	163,300**	189,000**
Subtotals		211,000	41,500	172,600**	214,100**
Summary	1	761,500	161,000	157,400	318,400
	2	783,300	114,300	259,400**	373,700**
Totals		1,544,800	275,300	416,800**	692,100**

*Numbers are rounded to the nearest $100 thousand.

**Includes $150 million for astrophysics high angular resolution imager.

B. DISCIPLINES

B.1. Chemistry

Large facilities are playing an increasingly important role in chemical research. It has been an evolutionary process, starting with opportunities provided by large instrumentation and moving to facilities comprised of clusters of large integrated instrumentation/computational facilities in regional spectroscopic facilities.

Ultra high vacuum chambers with sophisticated analytical instrumentation using laser, electron, and ion cluster beams, together with various spectrometers, are mandatory for leading edge research in many areas of chemistry. Lasers have become important analytical tools to study the dynamics of chemical reactions and to photoinduce reactions. These instruments are usually short wavelength visible or ultraviolet tunable lasers that are themselves pushing the limits of laser technology and hence require considerable expertise and expense to operate and maintain. In addition, many research projects are concerned with the chemistry of materials processing, such as integrated circuit fabrication, that demand clean room facilities by their very nature.

In order to remain globally competitive, particularly in areas of chemistry of importance to DOD, it has been recently recognized that traditional chemical research laboratory facilities at universities are in serious need of upgrading and that shared centralized new facilities are necessary due to the high costs of the instrumentation and environmental control required. This evaluation applies to the two topical areas identified by DOD research managers as candidates for facilities upgrading, based on scientific opportunities and on laboratory needs. These priority topics are laser chemistry and polymeric materials.

Lasers have become a valuable tool in many branches of chemistry. Catalytic activity and selectivity can be studied by using laser Raman spectroscopy to determine the vibrational modes and polarization of structures of molecules adsorbed on single crystal surfaces. High powered photo-ionizing lasers can be used in conjunction with ion cyclotron resonance spectroscopy to study the role of metal ions as selective chemical ionization reagents. Laser induced fluorescence of metallic ions and subsequent transfer of energy to neutral ions may yield superior detection limits, compared to well established analytical techniques that employ fluorescence of neutral metal ions in flames. Two step laser photo dissociation of small molecules can be used to elucidate isotope separation and enrichment processes. In this latter process, an intense pulsed infrared laser vibrationally excites molecules containing the chosen atomic isotope and a second ultraviolet laser photodissociates the molecule, allowing the desired atomic isotope to be collected from the photo fragments. These examples indicate the utilitarian richness of lasers in modern chemistry and illustrate that often they are used in combination with other sophisticated analytical equipment. The facilities investment described here would establish fifteen laser chemistry centers

where the operation and maintenance of the lasers would be accomplished by support specialists to serve several research projects. On an even larger scale of centralization, a single free electron laser facility would also be established to provide a very intense and widely tunable source of radiation.

Polymeric materials are found in most military equipment, because of their excellent chemical stability, mechanical properties, and low cost. The majority of the research support for improvements in these materials comes from industry in pursuit of commercial applications, although DOD does support some research specific to stringent military requirements. However, the polymer research of greatest interest to DOD, and for which university facilities upgrades are needed, concerns conducting polymers and polymeric approaches to structural composites, ceramics, and self-reinforcing polymers. It is important to note that independent industrial support of research in these areas is minimal or not aimed at DOD needs.

Conducting polymers that would combine the processability, durability, and light weight of plastics with the electrical conductivity of metal would find a wide range of applications in military systems ranging from solar cells and batteries to integrated circuits and stealth structures. Polyacetylene was the first organic polymer to exhibit electrical conductivity that could range from that of glass to that of metal, depending on the amount of dopants introduced. Doping methods have expanded to include solution doping, ion implantation, and electrochemical doping. Other new polymers have been made conducting, including polypyrrole and polythiophene. Polymer processability and stability are degraded by the doping methods currently used to induce conductivity. Much research is directed at improved doping techniques and on incorporating conducting polymers into nonconducting polymer matrices, as well as fundamental studies to explain the mechanism of electroactivity.

Fiber reinforced composite structural materials are finding many engineering applications, some of which are described under Materials and Engineering. Examples of the Chemistry research topics include organometallic polymer precursors for producing the fibers and self-reinforced or ordered polymers to attain the mechanical properties of fiber-reinforced composites without the need for fiber reinforcement. The most notable of the self-reinforced polymers developed under DOD sponsorship is polybenzothiazole (PBT), which exhibits an extended rigid chain alignment at the ultra-structural level. It offers low-cost processing, by casting and extrusion, instead of the sequence of weaving fibers, stacking of many thin plys, and curing at high temperature required for conventional fiber-reinforced composites.

Other polymeric materials research includes biopolymers, such as the polysaccarides for reduced hydrodynamic drag and non-linear electro-optic polymers for optical signal processing applications. The facilities investment described here would provide the polymer processing and characterization facilities for several focused centers of university research on electrical, optical, magnetic, and structural polymers.

B.2 Electronics

In addition to the traditional subject areas of electronic devices, circuits, and systems, the Electronics research program of DOD encompasses elements of information processing, low energy laser physics, optics, and material growth. For the purposes of this study, the facilities required for the growth of electronic and optical materials are reported under Materials and the low energy lasers, optical circuits, and vacuum tube research facilities are reported under Physics. The information processing research, being closely related to computer science, is not discussed, since, as mentioned in the Introduction, the National Science Foundation (NSF) and the Department of Energy (DOE) have major facilities programs in progress to provide scientific supercomputing access to university researchers. DOD, through the modernization program of the Defense Advanced Research Projects Agency (DARPA), recently made a significant upgrade in university computing facilities for symbolic computing in anticipation of the thrust in strategic computing. The Office of Naval Research is making available to its principal investigators a significant portion of the time of the Naval Research Laboratories' supercomputer at no cost to the existing research contracts.

A strong and clear consensus has emerged from this study indicating that the research managers of the Electronics program within the DOD feel that microcircuit fabrication at dimensions much smaller than those of the Very High Speed Integrated Circuits (VHSIC) program represents the greatest opportunity and greatest research facility need within Electronics. The feature sizes desired are 10 to 100 times smaller than the one-micron regime currently being advanced under VHSIC. It is in this regime that entirely new modes of operation of electronic, optical, and magnetic devices occur, due to the quantum effects produced by the limited number of atoms contained within these small dimensions. These phenomena present the possibility of creating devices whose performance can be greatly superior to that predicted from the bulk characteristics of the material from which they are fabricated. This has already been observed for high speed field effect transistors (FETS), when the device dimensions are reduced below one-tenth micron. It has also been observed that dramatic increases in transmission properties of optical materials occur when very thin layers of material are stacked in a multilayer sequence, offering the possibility of improved photodetectors and lasers.

The fabrication of these novel devices requires very advanced and expensive equipment for the deposition, lithography, and selective removal of the deposited materials. In addition, sensitive analysis of the surfaces and interfaces between dissimilar materials needs to be performed during the fabrication process. This is in contrast to current commercial practice (even for sophisticated microcircuits), where the analysis by electron microscopes and spectrometers is accomplished after the circuits are removed from the fabrication apparatus and before they are inserted into the next apparatus in the fabrication sequence. This requirement for in-situ analysis has greatly increased the minimum cost of doing research on device fabrication.

The facilities in which this instrumentation is housed require extreme control over air purity, to avoid dust particle disruption of the fabrication, and extreme control over vibration, to avoid misalignment of

the successive patterns employed in the fabrication sequence. The reliability of these as yet undeveloped circuits is anticipated to be a major concern that is best addressed early in their development, since the failure phenomena are anticipated to be inextricably tied to the fabrication process employed at the microscopic level.

For these reasons, the first priority in microcircuit fabrication was given to the refurbishment and upgrading of up to six university centers for microcircuit fabrication, with a second priority of augmenting two university reliability research centers to work closely on this new class of circuits.

In a separate, but related, research area, reliability at the systems level is perceived to be threatened today by the susceptibility of advanced solid state circuits to electromagnetic interference at relatively modest power levels. Research into hardening weapons systems against intentional enemy electromagnetic interference or inadvertent disruption by radiation from nearby friendly systems is required. The facilities for enabling university participation in this research include anechoic chambers and electromagnetic measurement instrumentation as a first priority, and dedicated computational facilities for modeling as a second priority.

B.2. Engineering

Engineering encompasses the disciplines usually associated with university departments of mechanical engineering, aeronautics and astronautics, civil engineering, industrial engineering, and materials engineering. The subject matter frequently overlaps that of the other disciplines, such as Materials or Chemistry, but is usually closer to a specific end application or requirement. For example, composite structures is a thrust area that has the same ultimate goal as Materials research on structural composites, namely lighter weight and stronger structures for building weapons platforms. The distinction is the focus in Engineering on determining the performance of composites through innovative design and analysis of structures using state-of-the-art materials. Research results are fed back to materials scientists to provide guidance to their endeavors. A base of knowledge about optimal design methods is thereby developed for application to many problems. Proceeding with this example, non-destructive evaluation (NDE) techniques must be developed to enable the engineer to perform these measurements in support of the analysis of composite structures. There is considerable resultant interaction with the materials scientists who also need NDE techniques to evaluate their progress in controlling the composition of materials.

Similarly, the area of Energetic Materials and Combustion involves considerable interaction with chemists to improve propellants, explosives, and fuels. The facilities in these two areas are typically large and have a significant element of concern for the safety of the personnel performing the research. The instrumentation is becoming dominated by lasers and analytical tools similar to that needed in Materials science.

Fluid mechanics and acoustics are the classical, almost exclusive, domain of Engineering, with slight involvement by molecular and chemical

physics. The facilities are typified by dedicated wind tunnels and water tunnels. Instrumentation is dominated by automatic digital data acquisition and digital computer modeling and simulation of the phenomena. Laser probes and acoustic sensors with sophisticated signal processing are also mainstays of instrumentation in this discipline.

Manufacturing, design, and reliability have increasingly been moving toward a computer-dominated emphasis on graphics, design aids, expert systems for process control, artificial intelligence to relieve pilot workload in single seat helicopters, and self diagnosis and self repair of machines and weapons systems. Classical industrial engineering, computer science, and structural engineering are very much coming together in this field. The facilities are replicas of factory workcells or simulators of aircraft cockpits and the instrumentation is heavily computer networked. The Defense Advanced Research Projects Agency (DARPA) is making advanced teleconferencing equipment available to several university centers in robotics so they may test their algorithms for robot vision on the DARPA autonomous land vehicle located at a contractor facility. They will also plan to provide replicas of a fingered robot hand to many of these university research centers. Non-destructive evaluation for manufacturing process monitoring and control, as well as for inspection of finished parts and fielded systems, requires a comprehensive research program, which would best be accomplished through a center of excellence in non-destructive evaluation/characterization.

Soil mechanics is uniquely supportive of blast hardened silos, construction, maintenance, and repair of runways, and priority command, control, and communications centers. The facilities at universities are presses, shock tubes, or high-G centrifuges.

B. 4. Materials

Materials research includes the growth of semiconductor, magnetic, and optical materials, as well as processing and fabrication of structural materials such as metal alloys, ceramics, and composites. The processing of semiconductor materials into electronic and optical devices and circuits is reported under Electronics, while the testing of structural composite materials and non-destructive evaluation for both manufacturing and in-process control of materials is reported under Engineering. This traditional division of research responsibility has begun to blur in recent years, and multidisciplinary research teams have been forming in recognition of the strong interaction between material growth, component fabrication, and ultimate system performance. In fact, for optimum coordination, the facilities requirements reported in this section for compound semiconductor growth should be co-located or closely adjacent to the microelectronic fabrication and reliability facilities reported under Electronics.

The greatest potential payoff and also the greatest investment costs are perceived by DOD materials research managers to be associated with two areas: the growth of compound semiconductors and the fabrication of advanced structural composites. High priority at somewhat reduced investment is given to facilities for optical and magnetic materials and for research on structural ceramics.

Compound semiconductor growth has received only a small fraction of the scientific and technical attention that has been spent on silicon. This has been entirely justified to date, since silicon possesses excellent electrical, thermal, and chemical properties, especially with its high quality native oxides and silicides. Being an elemental semiconductor, silicon is significantly simpler from a device processing standpoint than the compound semiconductors, such as gallium arsenide, cadmium telluride, and alloys, e.g. gallium aluminum arsenide and mercury cadmium telluride. The steady doubling of the capability of silicon integrated circuits every two to four years for the past twenty years is evidence of the wisdom of this research investment strategy. It is only recently that the material property limitations of silicon have presented a serious limit to device performance. Research attention is currently turning to at least three ways to get around this limitation. One approach is mentioned in the Electronics section, having to do with new device physics associated with ultra small device dimensions. A second approach, for information processing, is to use artificial intelligence to make "smarter" rather than just "faster" computers. The third approach is to turn significant resources toward the growth and characterization of the compound semiconductors. The facilities investment that is detailed here would permit four to seven university centers to advance the technology of compound semiconductors for signal detection, signal processing, millimeter waves, and communications, to name just a few DOD priority applications.

Composites materials have similar exciting potential for structural applications, ranging from high strength, lightweight airframes and large space structures to lightweight armor for highly mobile combat vehicles. These materials utilize high strength fibers embedded in polymeric, metal, or ceramic matrices. The creation of the fiber itself and the interaction between the fiber and the matrix during the processing largely determine the performance and reliability of the composite when exposed to harsh military environments over its service life. Only recently have advances in analytical tools permitted the microscopic characterization of these materials, both physically and chemically. These tools are both elegant and expensive. The facilities investment detailed here would establish, through new construction and refurbishment, six centers of university research on structural composite materials.

Optical materials are beginning to emerge in communications and signal processing applications. The advances that have been made in optical waveguides using silica glass exemplify the success possible through materials processing research. The combined stringent requirements for low transmission loss and very high tensile strength were achieved through research linking materials structure, properties, and performance. Magnetic materials in bulk form are widely used in critical electrical components, such as electromechanical switches and microwave phased array transmitters and receivers. In thin film form, magnetic materials are used for recording media and non-volatile memory. The facilities investment described here would establish two university centers in optical materials and would augment one existing university center in magnetic materials.

Structural ceramics research of high quality is performed in a number of small university laboratories that are in need of refurbishment and expansion to apply modern microstructural analysis techniques to

processing of high temperature ceramics for hostile environments. Both bulk ceramic components, such as radomes for high velocity aircraft, and ceramic coatings on turbine engine components would benefit from this upgraded research capability.

Finally, it should be noted that a segment of the materials research community is dependent upon support from very large research facilities, such as synchrotron and neutron sources. None of these facilities are included in this report. The predominant funding for these national facilities comes from NSF and DOE, with only minor support from DOD. Any decrease in support of these facilities by the other agencies would severely affect the DOD Materials research program.

B.5. Physics

Research on new and improved sources of electromagnetic radiation is a major component of the Physics program of DOD. The free electron laser is a direct result of high risk research funded by DOD. It has demonstrated an entirely new mechanism for generating coherent radiation that is freed from the usual constraints imposed by the need for a material medium. This device has already demonstrated that very wide tunable bandwidth is possible; this has great implications for its utility as a scientific research tool in the analysis of materials, and as a frequency agile radiation source for potential military applications, such as communications and target tracking. Recirculating the electron beam in storage rings offers theoretically high efficiency and hence the potential of high power free electron lasers for directed energy weapons application. The facilities investment reported in this section under coherent radiation sources would refurbish and upgrade three to four existing laboratories performing research on these novel sources.

More conventional lasers for a variety of wavelengths are being explored as tools for research on ultra small integrated circuits, optical computing, catalysis, and molecular biology and for tactical warfare applications such as target designation, optical jamming, and covert communications. The first demonstration of the use of a finely focused laser beam to deposit micron-sized metal connecting lines on semiconductor surfaces occurred under DOD sponsorship in the last five years. It was immediately picked up by the integrated circuit manufacturers as a tool for repairing defects in expensive integrated circuits, and in the photomasks used to produce the circuits. Prior to this breakthrough, lasers had only been used to remove excess material from circuits by vaporizing short circuits and trimming resistors to tolerance. This research continues today under DOD sponsorship and is demonstrating novel methods of doping circuits and of depositing insulators and conductors.

Other laser research projects are attempting to leapfrog over the limitation foreseen in silicon integrated circuits that results from the fact that as much as three-quarters of the surface of these circuits is devoted to metal interconnecting lines between the hundreds of thousands of constituent transistors. The propagation delay of the signals moving on these interconnects at the speed of light is becoming more important in determining the circuit speed than is the switching speed of the transistors. Optical computing chips afford the prospect of distributing the signals by laser beams to many portions of the circuit simultaneously,

thereby avoiding the input-output bottleneck of electrical integrated circuits. The facilities reported under optical communications and spectroscopy in this section would establish a new center for optical circuitry and would upgrade an existing laboratory for optical communications.

Directed energy devices require large facilities for research. The high voltages and currents required can only be stored and switched by physically large components as dictated by the scaling laws of electrical power engineering. To some extent this represents a departure from the usual scale of university research funded by DOD, since "big physics" is usually supported by NSF or DOE. DOD has funded university centers in pulsed power, but this has represented only approximately 10 percent of the physics budget. The facilities described under directed energy devices would expand the existing pulsed power centers and upgrade other centers for research on accelerators and microwave and millimeterwave high power sources. Beam propagation and the interaction of electromagnetic energy with materials would also be studied at these centers.

Astrophysics research directly produces knowledge of the background radiation against which space objects must be detected. Secondarily, the advances in instrumentation (optics, infrared, and x-ray) needed to conduct this research improve our military capability to detect and track space objects and to detect nuclear events in space. The major facility upgrade in this section, and indeed, the single highest cost item in the entire report is a $150M high angular resolution imager center whose goal is a hundred-fold increase in image sharpness on celestial objects and space vehicles.

C. SUMMARIES

Laboratory facilities and equipment needs for thrust areas associated with the foregoing disciplines are given in the following summaries. The science and technology implications of laboratory enhancements, and their national security consequences are also addressed.

CHEMISTRY

Thrust Area: Laser Chemistry

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	20,000	3,000
	-- Priority 2 --	
New construction	75,000	9,000
Renovation/expansion	150,000	13,500
Subtotal	245,000	25,500

Equipment: Linear accelerator and storage ring electron sources; upgrade equipment for free electron laser facility to enhance short wave-length beam power; arrays of six lasers (dye, argon ion), with diagnostic, data processing, and beam direction equipment for each of 15 laser chemistry centers.

Priority	Cost ($ thousands)
1	7,000
2	30,000
Subtotal	37,000

Total Cost: $62,500,000

Technical Objectives and Opportunities:

-- Priority 1 --

An upgraded free electron laser laboratory would be established. It would be a high power, high time resolution facility essential to progress in chemical reaction kinetics, surface physics and chemistry, hot carrier electron transport investigations, and high resolution photo emission studies.

-- Priority 2 --

Fifteen laser chemistry centers would be established. This number represents a best estimate of university community requirements to ensure that DOD-sponsored research in the field is conducted in an efficient, cost-effective manner. Centralized laser resources would facilitate the sharing of expensive instrumentation and permit a reduction of maintenance costs through the pooling of technicians and shop facilities. The centers would include picosecond lasers which, especially in the ultraviolet region, offer a new tool for studying the dynamics of chemical reactions.

National Security Consequences: Fundamental knowledge of chemical reactions is crucial to much of military technology, e.g., to the improvement of propellants, explosives, fuels, lubricants, and high energy lasers.

CHEMISTRY

Thrust Area: Polymeric Materials

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	15,000	2,000
	-- Priority 2 --	
New construction	170,000	20,500
Renovation/expansion	17,000	1,700
Subtotals	202,000	24,200

Equipment: Polymer molding; film casting; film and fibers drawing/orientation equipment; integrated scanning transmission electron microscopes and x-ray detector systems; SQUID magnetometers; picosecond spectroscopy systems; Fourier transform nuclear magnetic resonance units; electrophoresis equipment; data processing and analysis instrumentation; dedicated computer resources.

Priority	Cost ($ thousands)
1	7,000
2	3,350
Subtotal	10,350

Total Cost: $34,550,000

Technical Objectives and Opportunities:

-- Priority 1 --

Laboratory upgrades would provide significant capabilities for new polymer research at the molecular level, heteroatom polymer synthesis and characterization, characterization of polymers for electronics, etc. Focused centers would be established for the development of a) a new generation of polymers for electronics, optical, and magnetic applications, and b) composite materials with unprecedented toughness and high temperature capabilities.

-- Priority 2 --

The proposed expenditures would greatly enhance research in the areas of composite materials, ordered structural polymers, and polymer thin films for electronics applications. This in turn would lead to the development of improved dielectrics, capacitors, and electroactive polymers for uses such as piezoelectric sensors.

National Security Consequences: Polymer materials are essential elements of virtually all strategic and tactical weapons systems. High temperature metal matrix and ceramic matrix composites for applications such as radiation-hardened structures and gas turbine blades require high temperature fibers. Other applications include cheap, expendable acoustic detectors for sonic buoys, and a variety of electronic microdevices. Improvements in polymeric materials would enhance the performance, reliability, and maintainability of a wide array of weapons systems and logistics equipment.

ELECTRONICS

Thrust Area: Microelectronic Fabrication and Reliability for Unique DOD-Critical Devices/Materials

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	60,000	30,000
Renovation/expansion	60,000	15,000
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	20,000	4,000
Subtotal:	140,000	49,000

Equipment: Vacuum and plasma deposition; electron beam and x-ray lithography; plasma etching; wet chemical etching; impurity analysis with electron and ion beams; computational support for device modelling and process simulation; environment simulators for temperature, humidity, vibration, and synchrotron light source for surface diagnostics.

Priority	Cost ($ thousands)
1	30,000
2	6,000
Subtotal:	36,000

Total Cost: $85,000,000

Technical Objectives and Opportunities:

-- Priority 1 --

Provide vibration-free facilities for extremely small feature-size (one hundred angstrom) micro-circuit fabrication of devices utilizing technology beyond VHSIC. Electron-beam and x-ray lithographic equipment and plasma and laser enhanced photo deposition apparatus are required. Electron and ion-beam imaging systems for measurement analysis of ultra small structures are necessary.

-- Priority 2 --

Establish research capability in reliability of micro-circuit devices, especially with respect to temperature, humidity, and radiation hardness of ultra small devices. Expand synchrotron analysis capability for analysis of electrical contacts and other natural interfaces.

National Security Consequences: Integrated circuit fabrication is pressing the limits of our knowledge of chemistry and physics, particularly of interfaces between materials, and the utilization of unique materials for DOD devices. Research to provide the knowledge required for further advances in integrated circuits can only come if researchers in university laboratories have access to state-of-the-art fabrication equipment and processes. Reliability of military systems using integrated circuits depends to a large extent on the processes used to fabricate circuits and their stability over time.

ELECTRONICS

Thrust Area: System Robustness and Survivability

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost $ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	10,000	4,000
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	5,000	2,000
Subtotal:	15,000	6,000

Equipment: Electromagnetic generators; anechaic chambers; microwave measurement equipment; propagation ranges; computation facilities for modelling and diagnostics.

Priority	Cost ($ thousands)
1	3,000
2	2,000
Subtotal:	5,000

Total Cost: $11,000,000

Technical Objectives and Opportunities:

-- Priority 1 --

Expand existing facilities for the measurement of electromagnetic propagation, measurement, and system network investigations.

-- Priority 2 --

Provide computational facilities to enhance modeling of electromagnetic interference phenomena.

National Security Consequences: Sophisticated weapon systems are potentially vulnerable to electro-magnetic interference, either consciously induced by enemy forces or unintentionally introduced through radiation from friendly force equipment. Subtle interactions between electronic systems operating on the same platform can degrade performance or completely deny weapon systems availability. Fundamental scientific understanding of means for minimizing these effects is required to supplement the current engineering fixes being pursued.

ENGINEERING

Thrust Area: Combustion

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	57,500	9,250
Renovation/expansion	95,000	8,600
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	9,300	1,250
Subtotal	161,800	19,100

Equipment: Variable high-pressure flow reactors; optical diagnostic instrumentation; chemical analysis instrumentation; vector processors for the simulation of turbulent multiphase processes; dedicated computer diagnostic and analysis capabilities.

Priority	Cost ($ thousands)
1	15,000
2	11,750
Subtotal	26,750

Total Cost: $45,850,000

Technical Objectives and Opportunities:

-- Priority 1 --

Conduct research on improving the energy efficiency of turbine and internal combustion engines, investigate the viability of alternate fuels (e.g., methanol), develop insights into high-pressure, high-temperature combustion chemistry of present and future propulsion fuels, study multiphase turbulent reacting fuels, and observe high altitude and high mach number combustion processes.

-- Priority 2 --

Develop unique facility for studying combustion and plasma phenomena of propulsion systems; anticipated benefits include increased understanding of ramjet and rocket motor instabilities, fire propagation phenomena ignition and flame propagation mechanisms, and plasma/gas dynamic interactions. Upgrade facility for quantitative flow field imaging to advance understanding of phenomena underlying energy conversion, aerodynamics, and propulsion processes.

National Security Consequences: Improve the range, performance, and reliability of aircraft, missile, ship, and land vehicle propulsion systems; enhance payloads, lower operating costs, reduce corrosion and detectable exhaust signatures, increase fuel performance, and reduce engine development time.

ENGINEERING

Thrust Area: Composite Structures

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	5,000	1,180
	-- Priority 2 --	
	N/A	
Subtotals	5,000	1,180

Equipment: Mechanical testing devices capable of multiaxial and variable loading rates in high temperature environments; real-time non-destructive ultrasonic, acoustic emission and x-ray radiography testing equipment; high temperature test equipment with associated data processing and dedicated computational capability.

Priority	Cost ($ thousands)
1	3,420
2	---
Subtotal	3,420

Total Cost: $4,600,000

Technical Objectives and Opportunities:

-- Priority 1 --

Composite materials have not been exploited to the degree possible, due to a lack of detailed understanding of their response to complex loading conditions, high strain rates, and hostile environments. The proposed facility would likely engender major advances in the understanding of the thermomechanical behavior and failure characteristics of composite materials, with emphasis on high temperature conditions.

-- Priority 2 --

N/A

National Security Consequences: Military applications of composite materials include engine hot sections, nozzles, missile nose cones, aircraft surfaces, lightweight high-strength materials, etc. Improved materials are key to enhancing the performance and maintainability of weapons systems and logistics equipment.

ENGINEERING

Thrust Area: Energetic Materials

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	---	1,000
	-- Priority 2 --	
	N/A	
Subtotals	0	1,000

Equipment: Mechanical and x-ray diagnostic devices; time-resolved optical spectrometer; electromagnetics effects sensor; gas guns; sample preparation equipment; specialized machine shops.

Priority	Cost ($ thousands)
1	7,000
2	---
Subtotal	7,000

Total Cost: $8,000,000

Technical Objectives and Opportunities:

-- Priority 1 --

A primary objective is the development of a broad class of high performance propellants. A second priority objective is research on energetic materials (explosives, propellants, etc.) which remain inert under shock conditions. This involves theoretical and experimental investigations of atomic and molecular processes in shocked condensed wave materials. Experimental research would provide time-resolved optical, x-ray, electrical, and mechanical diagnostics on materials stimulated by mechanical impactors or lasers.

-- Priority 2 --

N/A

National Security Consequences: Inadvertent ignition of explosives and propellants under mechanical shock and thermal stress is a significant operational hazard, particularly under combat conditions. The development of energetic materials which a) are relatively inert to those stresses, and b) function optimally on command, would mitigate this problem.

ENGINEERING

Thrust Area: Fluid Mechanics and Acoustics

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	7,000	650
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	---	350
Subtotals	7,000	1,000

Equipment: State-of-the-art instrumentation for physical acoustics research including highly stabilized lasers, cryogenic equipment, and digital processing gear for automating signal detection and data processing; instrumentation and support equipment for wind and water tunnel facilities for the upgrading of data acquistion and reduction capabilities. For water tunnels, traverse mechanisms, non-linear wave generators, current generators, and related measuring instruments are needed. Wind tunnel requirements include a multi-axis, three-dimensional laser doppler anemometer, and equipment for generating oscillatory flows.

Priority	Cost ($ thousands)
1	3,600
2	3,350
Subtotal	6,950

Total Cost: $7,950,000

Technical Objectives and Opportunities:

-- Priority 1 --

-- Wind tunnels facilities - provide a national resource for studying turbulent and unsteady flows in Reynolds number regimes typical of subsonic flight, and a second facility devoted to the study of the physics of separated flows and transitioning boundary layers. This research could lead to the development of revolutionary concepts of, and predictive methods for, flow management and control in the flight vehicle environment.

-- Water tunnel facility - upgrade an existing facility to greatly reduce flow noise inherent in present tunnel configurations. This improvement would facilitate research on reducing flow noise due to turbulent boundary layer flow around ship hulls.

-- Priority 2 --

-- Wind tunnel facilities - modifications at two sites to facilitate a) research on the prediction of the transition from laminar to turbulent flow

and its impact on vehicle drag, and b) low turbulence flow phenomena with emphasis on associated viscous effects, leading to improvements in aircraft design and control technology.

-- Studies of nonlinear surface wave mechanics to enhance understanding of wave/wave/current interactions, ocean wave/ship wake interaction processes, and associated underwater acoustics, leading to improvements in ship designs, wake signature reduction, etc.

-- Integrated physical acoustics laboratory to facilitate research in sound propagation and attenuation, molecular and chemical physics, and underwater acoustics.

National Security Consequences: The proposed facilities enhancements would support research critical to improved aircraft performance, range, payload, and fuel efficiency. Defense applications of water tunnel upgrades include improved range and performance of ships (surface and submersible), reduction of noise signatures of submarines, and enhanced performance of acoustic sensors through the reduction of host-sensor interference.

57-279 O - 87 - 46

ENGINEERING

Thrust Area: Manufacturing, Design, and Reliability

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	77,000	9,250
Renovation/expansion	55,000	6,250
	-- Priority 2 --	
New construction	10,000	1,200
Renovation/expaansion	20,000	4,500
Subtotals	162,000	21,200

Equipment: Hardware and software for design of component inspectability and manufacturing process control functions; integration of advanced non-destructive testing capabilities with computer-aided mechanical design methods; modernization of dynamic track facility including electronic sensors and displays, simulators, and noise and vibration sensors; human factors diagnostic equipment; avionics gear; combustion diagnostic equipment.

Priority	Cost ($ thousands)
1	10,000
2	3,000
Subtotal	13,000

Total Cost: $34,200,000

Technical Objectives and Opportunities:

-- Priority 1 --

Advances in manufacturing methods having DOD-wide implications for reducing weapons system life-cycle cost, and for enhancing systems reliability, would be pursued. Ancillary objectives include reduced lead times and product development costs, improved productivity and quality control, and reduced inventory costs. A new, unique interdisciplinary manufacturing technology facility emphasizing optimal materials utilization and product reliability would be established. Emphasis would be placed on applications of artificial intelligence concepts to the manufacturing cycle. A second laboratory would be developed for studying the application of computers to the design, manufacture, and control of complex systems, and for the development of advanced composite materials.

Integrated, coordinated research into all aspects of rotorcraft design, manufacturing, and performance at two laboratories is a second objective of the proposed expenditures. Areas of concentration include computer-aided design and manufacturing of rotorcraft components, the study of human

factors problems associated with the workload of single pilots in a high performance rotorcraft, stability and control research, and combustion studies aimed at enhancing engine performance.

-- Priority 2 --

Factory of the future concepts would be explored combining manufacturing physics and artifical intelligence, with emphasis on the development of unmanned, self-diagnostic, and self-repairing machines and robots.

Upgrades of two more rotorcraft labcratories addressing the technical issues outlined for Priority 1 would be made possible, with emphasis on rotorcraft dynamics and avionics, respectively.

National Security Consequences: Procurement and maintenance cost-containment are key considerations in the DOD budget. The proposed facilities would support research directed toward these goals. Improved quality control would enhance product reliability. Army mobility rests to a great extent on rotorcraft (helicopter) performance capabilities, including speed, lift capacity, payload, and crash-worthiness. The proposed facility expenditures would address all of these factors in a much more comprehensive manner than is now feasible.

ENGINEERING

Thrust Area: Soil Mechanics

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
	N/A	
	-- Priority 2 --	
New construction	6,000	1,600
Renovation/expansion	---	---
Subtotal	6,000	1,600

Equipment: Four hundred G-ton centrifuge with support apparatus.

Priority	Cost ($ thousands)
1	N/A
2	200
Subtotal	200

Total Cost: $1,800,000

Technical Objectives and Opportunities:

-- Priority 1 --
N/A

-- Priority 2 --
The centrifuge would permit the study of soil and structure phenomena in realistic stress regimes not possible with present facilities. The laboratory would be developed to study both static and dynamic loadings.

National Security Consequences: Research would be applicable to the development of improved structures for missile silos and hardened tactical facilities.

MATERIALS

Thrust Area: Optical and Magnetic Materials

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	10,000	3,000
Renovation/expansion	15,000	2,000
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	10,000	2,000
Subtotal:	35,000	7,000

Equipment: Preparation and handling facilities; high vacuum furnaces; computer-controlled annealing ovens; fiber extrusion and cladding apparatus; grinding and polishing equipment; electron beam microscopes; laser diagnostic facilities; secondary ion mass spectrometers; electron spectrometers; Raman surface spectrometers; high field magnets; casting/grinding/magnetic aligning/sintering equipment operating in "oxygen-free" atmospheres.

Priority	Cost ($ thousands)
1	2,300
2	1,000
Subtotal:	3,300

Total Cost: $10,300,000

Technical Objectives and Opportunities:

-- Priority 1 --

Establish two university centers of excellence in optical materials for both fiber-optic applications and integrated optics circuits for signal processing. Facilities should include material growth, device fabrication, and evaluation capabilities. The centers would generate benefits in such DOD high pay-off areas as durable low loss fibers, laser sources in the ultraviolet and visible wavelength ranges, detectors in the 8-14 micron region, vapor processing/deposition processes, non-linear optical materials, etc.

-- Priority 2 --

Expand existing capability in magnetic materials for improvements in field strength and in temperature operating range of rare earth magnet materials. Research emphasis would be on materials characterization and structure definition using Mossbauer, x-ray diffraction, scanning transmission electron microscope, and neutron diffraction methods.

National Security Consequences: Optical materials are assuming greater significance to defense systems for surveillance, laser designation, and high energy laser weaponry. In addition, optical signal processing may provide an alternate to conventional integrated circuits for information processing. Magnetic materials are currently used in microwave transmitting devices, switching devices, and in non-volatile memory systems for crucial military information processing and communciation systems.

MATERIALS

Thrust Area: Silicon and Compound Semiconductor Growth

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	20,000	15,000
Renovation/expansion	40,000	8,000
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	40,000	10,000
Subtotal:	100,000	33,000

Equipment: Molecular beam epitaxy; metal organic chemical vapor deposition electron beam diagnostics; laser probe diagnostics; mass spectrometry.

Priority	Cost ($ thousands)
1	30,000
2	10,000
Subtotal:	40,000

Total Cost: $73,000,000

Technical Objectives and Opportunities:

-- Priority 1 --

Crystal growth facilities for low defect silicon and for device quality gallium arsenide and gallium aluminum arsenide are required. Instrumentation in this area combines growth with evaluation of materials within the same deposition chambers. By contrast, in commercial practice crystal growth of bulk ingots is performed in an activity separate from the evaluation of the grown material. These facilities are extremely expensive and are in the laboratory apparatus phase currently, with few commerical instruments being available.

-- Priority 2 --

Crystal growth facilities for advanced compound semi-conductors such as mercury cadmium telluride are required for the improvement of optical as well as electronic devices. Relatively little research has been done on the application of modern growth techniques to these compounds, largely because of the attention focused on silicon and gallium arsenide.

National Security Consequences: Integrated circuits are at the heart of most modern military systems, from command and control to smart weapons. The VHSIC program has made a major advance in the capability of these devices, by reducing the feature size down to the one micron regime. Future advances in this circuitry will require greater fundamental understanding of the functioning of conventional integrated circuits. For feature sizes even smaller than this, quantum effects will introduce wholly new device phenomena, presenting major opportunities for advancement in information processing capabilty. Examples of technology applications include infra-red focal plane array detectors, integrated optics, millimeter and microwave integrated circuits, and optoelectronics.

MATERIALS

Thrust Area: Structural Ceramics

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	20,000	3,000
Renovation/expansion	5,000	1,000
	-- Priority 2 --	
New construction	30,000	5,000
Renovation/expansion	10,000	2,000
Subtotal:	65,000	11,000

Equipment: Ball milling and mixing equipment; hot isostatic presses; vacuum and controlled atmosphere furnaces; fume hoods; surface analysis equipment; scanning electron microscopes; secondary ion mass spectrometers; x-ray diffractometers; computational facilities for data acquisition and process modelling.

Priority	Cost ($ thousands)
1	9,800
2	5,400
Subtotal:	15,200

Total Cost: $26,200,000

Technical Objectives and Opportunities:

-- Priority 1 --

Three university laboratories currently involved in ceramics research would be upgraded. The primary benefits include enhanced understanding of the fundamental relationships between (a) ceramics constituents and processing techniques, and (b) material properties, reproducibility, and reliability. Elucidation of these governing factors should greatly reduce the time required to develop improved ceramic materials and composites. Principal research benefits envisioned include development of non-destructive evaluation techniques, methods for the deposition of ceramic coatings using plasma techniques, and development of materials which will tolerate severe thermal shock and sustained high temperatures, and which have uniform, reproducible microstructures.

-- Priority 2 --

Three additional laboratory facilities would be expanded in the context of the above rationale.

National Security Consequences: In hostile environments, metal surfaces oxidize, corrode because of stress, fail because of fatigue, exhibit effects from laser radiation and interfacial phenomena, and are subjected to friction and wear. Ceramic materials are used in extremely hostile environments in turbine engines, rocket nozzles, and electromagnetic windows of high velocity aircraft and missiles.

MATERIALS

Thrust Area: Structural Composites

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	50,000	15,000
Renovation/expansion	60,000	8,000
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	80,000	10,000
Subtotal:	190,000	33,000

Equipment: Vapor deposition epitaxy reactors; filament winders; squeeze casting presses; injection molding presses; textile forming looms; thermoforming presses; servo-hydraulic forming equipment; powder processing and fiber growth equipment; special equipment for ceramics processing; high temperature/high pressure autoclaves; process control computers; diagnostic and modeling computers and graphics.

Priority	Cost ($ thousands)
1	20,000
2	20,000
Subtotal:	40,000

Total Cost: $73,000,000

Technical Objectives and Opportunities:

-- Priority 1 --

Establish four major university centers of excellence in the fabrication of fiber and matrix materials, emphasizing polymer matrix and ceramic matrix materials. Capabilities should include fabrication and layup of small samples and diagnostic materials for the analysis of thermophysical and thermomechanical properties.

-- Priority 2 --

Supplement the above with three to four additional university centers with similar missions.

National Security Consequences: Lightweight and high strength composite materials are increasingly being used in aircraft and spacecraft. These materials combine the high strength of ceramic fibers with the ductility of polymeric or metallic matrices. Significant performance advantages have already been obtained through the use of composite materials, including ceramic matrix composites, and further performance advantages are foreseen, particularly with regard to high temperature capability, laser hardness, armor, and low observables.

PHYSICS

Thrust Area: Astrophysics

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
	N/A	
	-- Priority 2 --	
New construction	68,000	11,550
Renovation/expansion	35,000	5,100
Subtotal:	103,000	16,650

Equipment: Radio, optical, and x-ray astronomy equipment; upgrade of 100 inch aperture telescope for active optics and interferometric imaging; high angular resolution imager with one milliarcsecond resolution and optical elements of 7 1/2 meters; 4-meter telescope for optical/infrared imaging and spectroscopy.

Priority	Cost ($ thousands)
1	N/A
2	152,065*
Subtotal:	152,065

Total Cost: $168,715,000

* Includes $150,000,000 for high angular resolution imager.

Technical Objectives and Opportunities:

-- Priority 1 --

N/A

-- Priority 2 --

- Expand laboratory capabilities in radio, optical, and x-ray astronomy to study final stages of evolution of stars, formation of neutron stars and black holes, the occurrence of supernova, and to elucidate recently observed non-thermal radio sources.

- Extend existing capabilities in active optics, speckle imaging techniques, and advanced detector programs to existing telescope to produce diffraction-limited imaging of astrophysical sources.

- Establish high angular resolution imager center which exploits advances in optics, sensors, and computer technology to afford a hundred-fold increase in image sharpness on celestial objects (quasar nuclei, stellar, and solar system object surface features) and space vehicles.

- Develop new optical and infrared telescope/instrumentation for astrophysics applications embodying improved precision pointing and tracking, image quality optimization, advances in optical and infrared technology, high speed two-dimensional photon detectors, etc.

National Security Consequences: Advances in astrophysics-related imaging techniques have important applications for the detection and identification of space and non-space objects of military significance. In particular, the technological development of active optics in combination with speckle imaging will make possible diffraction limited observations of objects through the atmosphere. The enhancement of x-ray instrumentation capabilities has application to the detection of nuclear events in space.

PHYSICS

Thrust Area: Coherent Radiation Sources

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	17,000	2,500
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	---	4,000
Subtotal:	17,000	6,500

Equipment: Tunable two-beam two-stage free electron lasers; millimeter range free electron laser; mode-locked laser and support equipment; spectrographs for optical emission spectroscopy; electronic processing equipment (lithographic, deposition, etching); auxiliary interface and support equipment.

Priority	Cost ($ thousands)
1	1,500
2	6,250
Subtotal:	7,750

Total Cost: $14,250,000

Technical Objectives and Opportunities:

-- Priority 1 --

Laser facilities are key assets for a variety of materials and directed energy related research. The cited expenditures would substantially enhance the capability of universities to explore and expand technology horizons in electronic materials, catalysis, corrosion, and molecular biology, among others. Emphasis is on more broadly tunable lasers, which generate coherent radiation over a wide range of energies. This greatly enhances the flexibility available to researchers for analyzing material properties, particular surfaces, and interfaces of importance to solid state electronics and optoelectronics.

-- Priority 2 --

Laser-guided plasma and electron beam facility upgrades will allow the university community to explore more efficiently and comprehensively heretofore unknown aspects of directed energy propagation concepts.

National Security Consequences: Coherent radiation research is critical to a variety of DOD R&D missions, including the design of directed energy weapons, propagation (e.g., "channeling") of charged particle beams, improvement of high power radar technology and electronic countermeasures, advances in ultra-small electronic devices, optical storage and switching aspects of ultra-fast optical computers, etc. High average moderate power tunable lasers are expected to have important implications for tactical applications related to electronic warfare.

PHYSICS

Thrust Area: Directed Energy Devices

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
New construction	---	---
Renovation/expansion	63,000	13,250
	-- Priority 2 --	
New construction	---	---
Renovation/expansion	20,000	4,000
Subtotal:	83,000	17,250

Equipment: Hardware to enlarge accelerator power supplies and capacitor banks; vacuum tube fabrication equipment; large electric discharge chambers; pulsed power generator; high-power glass laser; dedicated data acquisition and analysis computer facilities.

Priority	Cost ($ thousands)
1	6,250
2	4,000
Subtotal:	10,250

Total Cost: $27,500,000

Technical Objectives and Opportunities:

-- Priority 1 --

- Upgrade stellatron accelerator facility as a testbed for high current, high energy accelerators, including screen room and associated diagnostic instrumentation. Facility would generate data of use in the development of compact, high performance accelerators in the non-linear beam interaction regime.

- Establish center for research on thermionic sources of millimeter wave radiation at megawatt power levels. The facility would provide understanding electron-electromagnetic field interactions leading to the development of Rf sources in a regime extending to 30 THZ.

- Develop high repetition rate, high average power pulsed power facilities to support studies in plasma beam propagation, microwave power generation, and the interaction of electromagnetic radiation with materials.

-- Priority 2 --

- Expand center for research on switches and power conditioners for extremely high voltages and high currents. Research in this area is heavily dependent on the existence of specialized facilities.

National Security Consequences: Compact high current, high energy accelerators are key components in charged and neutral particle beam weapons concepts. Thermionic radiation sources are essential components of and/or have implications for fusion power sources, directed energy weapons, and spacecraft vulnerability questions associated with ion clouds in space. High voltage and high current switches, regulators, and storage devices are required to operate directed energy weapons. The development of repetitive and reliable opening switches would remove significant impediments to the practical implementation of all directed energy devices.

PHYSICS

Thrust Area: Optical Communications and Spectroscopy

Laboratory Needs

Facilities:	Building Requirements (gross ft^2)	Total Facility Cost ($ thousands)
	-- Priority 1 --	
	N/A	
	-- Priority 2 --	
New Construction	8,000	1,000
Renovation/expansion	---	---
Subtotal:	8,000	1,000

Equipment: Lasers (stable argon ion, ring, picosecond CO_2, femtosecond dye and YAG, mode-locked glass); transient digitizers; computational and digital signal processing capabilities; scanning electron microscope; optical components with special coatings.

Priority	Cost ($ thousands)
1	1,550
2	950
Subtotal:	2,500

Total Cost: $3,500,000

Technical Objectives and Opportunities:

-- Priority 1 --

Laboratory upgrade would facilitate research leading to a better understanding of the fundamental processes and interactions in semiconductors and microstructures necessary for the development of ultra-fast semiconductor electronic devices.

-- Priority 2 --

- Laboratory improvement would permit detection of weak signals which arise in many photon statistic experiments. For example, the creation of photon pairs through non-linear processes followed by subsequent simultaneous detection (i.e. correlation experiments) generally produces weak signals. Such phenomena could greatly expand communication signal detection capabilities.

- A Center for Optical Circuitry would be established for optical computing. It offers the possibility of great advances in computing speed, capacity, and degree of parallelism over electronic computing. Dramatic new computer architectures are possible, e.g., three-dimensional logic and storage.

National Security Consequences: A wide variety of defense-related technology improvements are based on progress in the development of extremely fast and compact electron devices for digital and analog applications. These include smart weapons and surveillance systems. In addition, secure optical communications have important applications to C3.

CHAPTER V

DISCUSSION AND RECOMMENDATIONS

A. DISCUSSION

The laboratory needs cited in Chapter IV relate to universities already heavily involved in conducting research for DOD. They represent a small subset of the 157 colleges and universities addressed in Tables III-4 and 5, and an even smaller segment of all research universities included in Tables III-2 and 3. The AAU study summarized in Table III-1 equates with this work most readily in terms of the number of institutions covered.

Summary comparisons follow between the prior laboratory assessments cited in Chapter III and the present work given in Chapter IV. It should be emphasized that these comparisons involve the DOD-specific laboratory needs developed in this report as opposed to more general needs addressed in prior studies. Nonetheless, they suggest that the cumulative expenditures discussed in Chapter IV are of reasonable magnitude in the context of general university laboratory needs identified in other studies.

- The AAU data shown in Table III-1 relate to 15 universities, a figure roughly equivalent to the average number of institutions encompassed by defense-related laboratory needs for each of the disciplines cited in Table IV-1. This probably accounts for the fact that, for some disciplines, defense-related totals substantially exceed the AAU report figures. Interpretations of these comparisons must be tempered by the fact that the discipline-specific university populations encompassed within the present study differ markedly from the AAU sample population. A Comparison of Tables III-1 and IV-1 indicates that the defense-related facilities needs cited in this report constitute 43 percent of the AAU Chemical Sciences projections for the period 1982-84, over 100 percent for Engineering (encompassing the Electronics, Engineering, and Materials categories of Table IV-1), and 55 percent for Physics. For projected equipment needs, those of this study exceed the AAU figures by factors of roughly three and six for Chemical Sciences and Engineering. The numbers are comparable for Physics, excluding the astrophysics high resolution imager cited in the present study.

- According to NSF staff, an estimated 50 percent to 70 percent of the $221 million cited in Table III-2 for 1983 university capital expenditures (research and instructional) was devoted to research laboratory facilities. Assuming, for purposes of comparison, a 60 percent figure, 1983 research laboratory expenditures for all universities in the engineering and physical science disciplines total $133 million. To obtain a roughly comparable figure, one can annualize the $275 million of defense-related engineering and physical sciences facilities needs (Table IV-1) over a five-year period. This yields an annual expenditure rate of $55 million. It represents slightly more than 40 percent of the estimated $133 million spent by all universities.

- Research equipment expenditures for all U.S. colleges and universities are summarized in Table III-3 for Engineering, Chemistry, and Physics and Astronomy. Engineering expenditures average approximately $70 million for the two-year period. The NSF Engineering category compares roughly to the combined Engineering, Electronics, and Materials categories of this report, where priority 1 and 2 equipment needs shown in Table IV-1 total almost $200 million. If the $200 million is annualized over a five-year period, approximately $40 million in FY 85 dollars would be spent for defense-related equipment annually. This represents over 55 percent of the average 1982-83 engineering annual equipment expenditures for all higher education institutions. Similar analyses for physics and chemistry suggest that needs in these areas cited in Table IV-1 pro-rated over five years are approximately $35 million and $9.5 million, respectively. The projected annual physics expenditure is roughly equal to the NSF 1982-83 average for all universities, largely due to a $150 million high resolution imager for astrophysics. Similarly, the projected chemistry annual expenditures are 30 percent of the average for all U.S. universities for the two-year period.

- Column two of Table III-4 lists 1982 research equipment expenditures for the top 157 research universities. As in Table III-3, the NSF Engineering category compares roughly to the combined Engineering, Electronics, and Materials categories of this report, whose equipment needs total approximately $200 million. Assuming again that expenditures for defense-related laboratory equipment needs would be spread over a five-year period, approximately $40 million in FY 85 dollars would be spent for this purpose annually. This represents roughly 45 percent of the 1982 expenditures for the 157 universities. Similarly, the five year annual expenditure level for physics from Table IV-1 is over 60 percent of the 1982 equipment purchase level, largely due to the inclusion of the aforementioned $150 million high resolution imager for astrophysics applications. The five-year expenditure level implied for chemistry in Table IV-1 is $9.5 million, or approximately 25 percent of the stated 1982 expenditures by the 157 universities.

- The replacement value of "academic research instrument systems in active research use" for the aforementioned 157 universities is given in Table III-3 in terms of 1982 dollars (Column 4). With an inflation factor of 1.076 applied to the 1982 costs, Table V-1 gives priority 1 and 2 (total) defense-related equipment needs from Table IV-1 expressed as percentages of Table III-5 replacement values. As before, the NSF Engineering category encompasses the Electronics, Engineering, and Materials categories of this report. For the Engineering and Physics and Astronomy categories, stated defense-related needs are quite substantial in comparison with the NSF equipment replacement figures. The Chemistry percentage is substantially lower, perhaps reflecting a proportionately lesser DOD involvement in broad aspects of experimental chemistry.

Table V-I

Defense-related university laboratory equipment needs (Table IV-1) expressed as percentages of replacement costs for all research equipment at 157 leading research universities (Table III-5)

Field of Research	% of Replacement Value
Chemistry	15
Engineering	44
Physics and Astronomy	68

B. RECOMMENDATIONS

A total of $300 million over a five (5) year period is proposed for the upgrading of university laboratories.

1. The priority 1 laboratory facilities needs cited in Table IV-1 should be addressed with incremental funding of a five-year $150 million initiative. The initiative should be a part of, and administered through, the existing contract research programs of the OXRs and DARPA. It is believed that this is the most efficient mechanism for targeting facilities improvement funds toward the highest DOD research priorities. This program would be of equal magnitude (i.e. $150 million expended at an annual rate of $30 million) to the existing University Research Instrumentation Program (URIP) pertaining to equipment, but would be allocated as facilities-earmarked increments to competitive research awards. It would thus differ from URIP in that it would not require the establishment of separate review and award mechanisms. It should be stressed that, in the best interests of national security, neither equipment nor facilities upgrade programs should be funded at the expense of existing OXR and DARPA competitive research programs. Further erosion of the latter would jeopardize the scientific basis for future technological innovation on which our national security depends.

2. The existing URIP program should be extended by three years at its present level of $30 million per year. This, combined with the remaining two years ($60 million) of the present program, would constitute the $150 million required to address priority 1 equipment needs (Table IV-1).

3. Priority 2 laboratory needs should be addressed as a national issue with the involvement of other federal agencies having an impact on the national science and technology base, i.e. the National Science Foundation, NASA, Department of Energy, etc.

4. Very large items of equipment and/or facility needs, e.g. the $150 million astrophysics high resolution imager cited in this report, should be addressed on their merits as individual appropriations rather than as parts of broader, more general funding initiatives.

APPENDIX

STUDIES OF ACADEMIC FACILITIES*

Study	Description of Study	Findings
"Health Related Research Facilities in the U.S. in the Nonprofit Nonfederal Sector" Study by Westat Corporation for National Institute of Health (NIH) (1969)	Survey study to gather data on the amount, age and ownership of space in 1968, the amount of space under or scheduled for construction and the estimated space needed to eliminate overcrowding by 1980	10 m. of 42 m. sq. ft. in unsatisfactory condition -over 50% available space in poor condition -additional 55 m. square feet of space needed by 1980, with 17 m. square feet requiring remodeling
"Higher Education General Information Survey" (HEGIS) Conducted by the National Center for Educational Statistics (NCES) (1974)	Survey of 3,200 colleges and universities including data to estimate facilities needs	-20% of facilities at surveyed institutions in need of replacement (2.3 billion square feet) -$2. billion needed just for remodeling of facilities
"Health Research Facilities: A Survey of Doctorate-Granting Institutions." Conducted by American Council on Education (ACE) with funding from National Science Foundation (NSF) and NIH (1976)	Survey of 155 Ph.D. granting institutions to gather data on status of academic health research facilities, new construction in progress, and plans for expansion in succeeding five year period	-29% of academic facilities for health research in need of renovation or replacement (23 million square feet) -cost estimates to meet needs: $547 million for 1975; $360 million for each of succeeding five years
"National Survey of Laboratory Animal Facilities and Resources" Conducted by National Academy of Sciences (NAS) (NIH Publication No. 80-2091) (1978)	Survey of 922 nonprofit NIH eligible institutions gathering data to estimate facilities needs	-16% institutions reported need for replacement of facilities -38% reported need for remodeling of facilities -47% reported need for additional space

Facilities Needs in Chemical Science and Engineering Conducted under aegis of the Board on Chemical Science and Technology, National Research Council (In progress)	Survey to ascertain specific facilities data for research and teaching in chemistry, biochemistry, and chemical engineering academic departments	In progress

APPENDIX 5

Department of Energy
Washington, D.C. 20585

August 21, 1984

MEMORANDUM FOR: Assistant Secretaries
Director, Office of Energy Research
Managers, Operations Offices

SUBJECT: Guidelines on Relationships Between the Department of Energy and Universities and Colleges

The Administration's commitment both to national security and strong economic revitalization includes a major emphasis on a strong national scientific and technical base. This emphasis, in turn, requires the active and cooperative participation of the three major Research and Development performing sectors—private industry, the government laboratories and universities and colleges.

The national energy effort, as one major component of the Administration's economic and national security programs, also requires close interaction of scientists and engineers in the three major sectors. University scientists and engineers are particularly important resources to the Department not only in producing new knowledge but also in preparing and training the next generation of scientific and technical professionals. Recognizing the importance of strong university-based participation in our programs, the purpose of this memorandum is to provide general guidance to Department offices and programs on how our relationships with universities and university scientists and engineers should be conducted.

Background:

The National Energy Policy Plan (NEPP) establishes overall goals and strategies for the Department in the planning, development, execution and evaluation of energy programs. The appropriate roles for the Department in supporting research and development are to advance the frontiers of basic scientific and technical knowledge and to support the development of new and alternative energy resources through scientific and technical research for further development and eventual utilization outside the government.

Institutions and organizations responsible for carrying out DOE-supported research programs include private industry, the major contractor-operated research facilities and laboratories, the Department's energy technology centers and universities and colleges. Each performer has important and distinct responsibilities in maintaining a strong technology base in all energy areas. The principal criterion used in selecting performers to carry out DOE research is excellence regardless of the location or type of performer. The competitive process provides assurance that the best research will be supported by the Department.

University Participation in Department of Energy Programs:

Within this research policy context, both the Department's fundamental science and energy research and development programs must continue to actively involve scientists and engineers in universities and colleges. This involvement is a national investment not only in the creation of new knowledge, but also in the education of highly-qualified scientific and technical personnel to meet future national needs. A major emphasis in DOE-university relationships should, therefore, be on supporting university scientists and engineers in the fundamental energy-related sciences and in research which strengthens the technology base in all energy areas. In addition, DOE-supported research should directly enhance the education and training process through the participation of students in research.

Further, DOE staff should encourage and support cooperative research and related programs between universities and industry and between universities and the national laboratories and energy technology centers. It should be noted that each performer, whether university, industry or national laboratory, operates in distinct and different environments. DOE staff should recognize these differences and apply management and administrative systems and techniques compatible with the needs and circumstances of each major performer, consistent with statutory and regulatory requirements.

Policy Guidelines

The following general policy guidelines should be used by DOE staff in developing relationships with the university community and in supporting and administering university-based research and related programs. Departmental staff should, to the extent practicable and appropriate and within legal and regulatory requirements:

- o involve university scientists, as appropriate, in all energy programs with the expectation that they will be significant performers in all disciplines related both to fundamental research and advanced, longer-term technology base research leading to improvements and new developments in the energy technologies;

- o provide appropriate opportunities for university scientists to make recommendations on the planning of energy research and technology development programs;

- o recognize the educational impact and benefits of advanced research by encouraging and providing support, as appropriate, for the participation of students in university research projects;

- o encourage university researchers to develop and pursue unique and innovative concepts and ideas in energy R&D including, where appropriate, research requiring multi and interdisciplinary research teams;

- o encourage interaction and collaboration in energy research among universities and industry, the national laboratories and the energy technology centers, including consideration of and support for joint research projects;

- o provide opportunities for faculty and students in predominantly minority universities, including the Historically Black Colleges and Universities, to participate in DOE research, both directly and through the national laboratories and energy technology centers;

- o expand opportunities for university researchers to utilize the special and unique facilities and equipment in the national laboratories and the energy technology centers;

- o work towards ensuring more consistent execution and administration of university research grants and contracts among all the cognizant field procurement offices; and

- o conduct the Department's overall relationships with the university community in a manner which reflects understanding of the special role of universities in education and research and avoids imposition of burdensome administrative requirements wherever possible.

Administrative Guidelines

The following administrative guidelines should be used in carrying out the policies stated above:

- o In addition to responding to competitive solicitations, university scientists should be encouraged to submit unsolicited research proposals to all programs. Program staff should make a concerted effort to provide appropriate advance information and guidance on agency objectives and programs relative to the type of effort contemplated by university scientists.

- o Specific staff members in Headquarters program offices, the energy technology centers, the operations offices, and the multiprogram national laboratories should be designated as initial points of contact for university scientists and administrators seeking information on research opportunities. These staff members will be generally familiar with program R&D needs, interests and procedures for handling and executing university proposals and awards.

- o DOE-sponsored research projects should recognize the special educational responsibilities of universities and normally should avoid support for shorterm, subprofessional types of work that do not contribute directly or significantly to the university's educational mission.

- o Reasonable continuity of university research projects should be maintained. Programmatic and administrative attention to timely award renewals and the use, where appropriate, of multiyear awards will help minimize adverse and burdensome effects on faculty and students and on the institution. Abrupt changes in the funding and monitoring of ongoing university research projects should be avoided wherever possible.

- o Reporting and other administrative requirements on university research projects should be held to the minimum consistent with effective implementation of business and program management oversight responsibilities.

The responsibility for strengthening existing and developing new university research programs rests with each Program Assistant Secretary and the Director of the Office of Energy Research. Each Assistant Secretary/Office Director is responsible for ensuring there are adequate opportunities for university participation in the programs under his/her jurisdiction. The Assistant Secretary for Management and Administration is responsible for ensuring that administrative and business management requirements on university research projects are applied as consistently as practicable and at the minimum level necessary.

I have asked the Director of the Office of Energy Research to report to me periodically on the extent the principles of this statement have been carried out. As necessary, he will prepare recommendations on how university participation in Departmental programs may be strengthened and improved.

Donald Paul Hodel

DONALD PAUL HODEL

Program-Dedicated Laboratories

THE SECRETARY OF ENERGY
WASHINGTON, D.C 20585

July 5, 1984

MEMORANDUM FOR Assistant Secretaries
Director of Energy Research
Managers, Operations Offices

SUBJECT: Policy Guidance for FY 1985-FY 1990 Multiprogram Laboratory Institutional Planning

The quality and usefulness of the multiprogram laboratory institutional plans have improved considerably since the first implementation of the formal planning process in 1978. Further improvement of the plans now depends upon improved mission definition for each laboratory and on improved program planning by the Department. I believe that the generic role of the multiprogram laboratories, recently approved by the Laboratory Management Council, constitutes a sound basis for defining laboratory missions (Attachment I). This role is to conduct high quality, nationally important basic research and applied research and development that, because of its nature, is more appropriately undertaken by national laboratories than by universities or industry. In fundamental research, the laboratories therefore focus on scientific areas of excellence that require large, capital-intensive experimental facilities, or that need sustained effort over periods of many years. In applied research, the focus is on nuclear weapons and defense-related activities, development of energy technologies involving large uncertainties and lead times, or important energy-related environmental factors.

What is needed now is an increasing focus, over the next several planning cycles, on the specific scientific and technical missions at each multiprogram laboratory. Your decisions on the types and levels of technical activity should take into account each laboratory's expertise and capabilities, and should complement other activity within the laboratory system, while maintaining scientific and technical competitiveness. The attached mission statements for each multiprogram laboratory are based on the current institutional plans and have been reviewed by the cognizant Secretarial Officers for consistency with the generic role statement approved by the Laboratory Management Council (Attachment II). I believe that these statements constitute a sound basis for discussion with the laboratory directors and for establishing more focused missions during this current planning cycle.

The Laboratory Management Council has recommended some additional steps aimed at maintaining and improving the effectiveness of the multiprogram laboratory system. As a result, during the past few months, we have issued the Department's policy on appraisal of laboratory performance, guidelines for the use of R&D exploratory funds, refinement of the lead mission assignment process, and a requirement that 5-year program plans include appropriate strategic guidance to the laboratories. These efforts should help to strengthen the institutional planning process and improve our overall interactions with the laboratories.

In addition, there is an important management effort underway aimed at reducing unnecessary and burdensome reporting requirements on the Field to a reasonable level consistent with effective accountability and management. I understand you have contributed to a review of Departmental directives and orders and have recently received a status report on the efforts of the Department to streamline procedures and reduce reporting requirements where possible. I urge you to continue to be involved in this important Departmental effort. It is my hope that it will result in a more effective relationship between the Department and its Government-owned, contractor-operated laboratories; one in which the Government is responsible for determining what is to be done and the contractor for getting it done in a manner consistent with good business practices.

The process for the current institutional planning cycle is underway. The cognizant Secretarial Officers are directing the process for their laboratories and will use it to reach broad agreement on the types and levels of technical activity that will be conducted by each laboratory through the planning period. The Director of Energy Research is coordinating the overall planning process and has issued the Department's schedule and instructions. I urge you in this institutional planning cycle to focus on laboratory technical missions and capabilities, and assign to the laboratories through improved Headquarters program planning, scientific and technical activities that are in keeping with their proper role and unique capabilities.

ATTACHMENT I

ROLE OF THE
MULTIPROGRAM NATIONAL LABORATORIES

The multiprogram laboratories conduct high quality, nationally important basic research and applied research and development that, because of its nature, is more appropriately undertaken by a Federal laboratory than by universities or industry. In basic research, the laboratories therefore focus on scientific areas of excellence that require large, capital-intensive experimental facilities, or that need sustained effort over periods of many years. In applied research, the focus is on nuclear weapons and defense-related activities, development of energy technologies involving large uncertainties and lead times, or important energy-related environmental factors. The laboratories also maintain for the Government the capability to provide independent scientific advice in their areas of expertise.

This undertaking requires the maintenance of broad multidisciplinary scientific capabilities and the conduct of research and development to support a technology base appropriate to each laboratory's missions. These capabilities are applied to national problems that are generally at the interface between the interests and capabilities of the university and industrial sectors, and that are of sufficient importance, size, term, and complexity to both benefit from and effectively use the laboratories' unique mix of skills and facilities. The laboratories interact and cooperate with the scientific and technical community, where feasible and beneficial, to achieve effective utilization of their unique facilities, to aid in education of scientists and engineers, and to enhance the transfer of technology to the public and private sectors.

Consistent with policies set forth in the National Energy Policy Plan, including strong support for federally-sponsored research and development, the generic role of the multiprogram laboratories can therefore be stated as:

- conduct basic research programs to advance the frontiers of our scientific and technical knowledge in physical and energy-related life and environmental sciences that involve large multidisciplinary teams or major, capital intensive experimental facilities, and provide use of those facilities to members of the scientific and technical community, including interested industry representatives or groups;

- conduct basic and applied research and technology development programs to explore energy technologies and related environmental factors, and develop research options in areas that involve large, unpredictable, and long-term risks, costs, or payoffs, that need development before they can reach the market as competitive energy investment options;

- conduct research, development, engineering, and technical and production support for nuclear weapons, associated nuclear materials, and other defense-related activities;
- provide research and development support, as appropriate, to other Government agencies, and make special capabilities available for public and private sectors on a reimbursable basis;
- contribute, through cooperative programs with universities, to the education of scientists and engineers in the fundamental sciences and all energy-related technologies;
- provide for and encourage the transfer of technology developed at the laboratories to the private and public sectors, and facilitate an interactive climate among the national laboratories and industry.

ATTACHMENT II

MULTIPROGRAM LABORATORY MISSION STATEMENTS

ARGONNE NATIONAL LABORATORY MISSION STATEMENT

The primary mission of Argonne National Laboratory is to carry out applied research and engineering development in nuclear fission and other energy technologies, and scientific research in basic physical and life sciences. This research and development is performed with emphasis on the linking of technology base research with engineering development throughout the concept to application stages. An important part of Argonne's mission is to design and provide research facilities for the benefit of members of the scientific and technical community, and to maintain close interaction with scientific personnel in universities and industry.

To fulfill its mission, Argonne focuses its scientific and technical efforts on: (1) nuclear fission, focused largely, but not exclusively, on the breeder and other advanced reactor systems, with emphasis on steam supply system technologies, advanced power conversion technologies, operation of test facilities, and innovative concepts utilizing inherently safe features and cost-competitive design; (2) nuclear fusion, focused on nuclear systems with emphasis on blanket technology development and materials research; (3) fossil energy, particularly advanced conversion systems with significant development efforts in related technologies; (4) solar and conservation, focused on development of innovative collectors, and energy storage and conversion systems; (5) basic research in physical sciences, focused on multidisciplinary efforts in chemistry, nuclear physics, high energy physics, and materials research; and (6) biological and environmental sciences concerning the effects of nuclear and non-nuclear emissions on living organisms.

BROOKHAVEN NATIONAL LABORATORY MISSION STATEMENT

The primary mission of Brookhaven National Laboratory is to design and provide large, complex research facilities for fundamental scientific studies, and to carry out basic and applied research in energy-related physical, life and environmental sciences. Brookhaven provides use of the laboratory's large and complex facilities to the scientific and technical community, and maintains close interaction with scientific personnel in universities and industry.

To fulfill its mission, Brookhaven focuses its scientific and technical efforts on: (1) high energy physics, presently centered on the operation of the Alternating Gradient Synchrotron; (2) nuclear physics, with current emphasis on heavy ion, kaon, and low energy physics; (3) life sciences research and nuclear medicine, focused on fundamental life processes and their alteration by radiation and chemical pollutants, and on medical applications of nuclear techniques; (4) materials sciences, centered on utilization of the National Synchrotron Light Source and the High Flux Beam Reactor; and (5) chemical sciences, with emphasis on fundamental research into chemical and physical phenomena underlying energy-related transfer, conversion and storage systems.

57-279 O - 87 - 47

IDAHO NATIONAL ENGINEERING LABORATORY MISSION STATEMENT

The primary mission of the Idaho National Engineering Laboratory is to furnish engineering services and products, principally in nuclear energy and associated technologies. Emphasis is placed on those areas which require, or particularly benefit from, the laboratory's unique facilities, geography, environment or expertise. Idaho provides use of its unique facilities for the benefit of members of the scientific and technical community, and maintains close interaction with scientific personnel in universities and industry.

To fulfill its mission, it focuses its scientific and technical efforts on: (1) defense-related nuclear materials production centered largely on receipt, storage and processing of spent fuels, and management of resulting wastes; (2) reactor development and operation, principally related to the Advanced Test Reactor and associated programs in materials testing, isotope production, irradiation services, and other training and test support; (3) waste management and waste technology development for the Low-Level and Transuranic Waste programs; (4) nuclear safety research; (5) service and support for other laboratories which have major facilities at the site; and (6) other energy research programs and support to the Department of Defense and the Nuclear Regulatory Commission.

LAWRENCE BERKELEY LABORATORY MISSION STATEMENT

The primary mission of Lawrence Berkeley Laboratory is to develop and utilize major research complexes centered around large experimental facilities, to carry out fundamental research in high energy and nuclear physics and in materials sciences, and to conduct applied research and development in energy technologies. Lawrence Berkeley provides facilities to qualified investigators, and capitalizes on its co-location with the University of California to maintain close interaction with scientific personnel in universities and industry, and to train scientists and engineers.

To fulfill its mission, Lawrence Berkeley focuses its scientific and technical efforts on: (1) nuclear physics, focused on heavy-ion investigations and complementary programs in light-ion nuclear science; (2) high energy physics, with emphasis on broad investigations in particle physics, and development of advanced detectors; (3) materials sciences, focused on basic research, and on basic and applied work at the Center for Advanced Materials; (4) magnetic fusion, in the area of neutral beam plasma heating technology; (5) basic research in physical and life sciences, with emphasis on carcinogenesis and mutagenesis studies, and on a wide spectrum of chemical sciences including actinide chemistry and chemical energy and chemical engineering thermodynamics; (6) medical research, with emphasis on the medical uses of accelerated heavy ions; and (7) conservation and renewable energy, principally in the buildings and transportation sectors.

LAWRENCE LIVERMORE NATIONAL LABORATORY MISSION STATEMENT

The mission of the Lawrence Livermore National Laboratory is to be a national resource of scientific, technical, and engineering capability, especially concerning national security. It undertakes those multidisciplinary fundamental and applied research and development activities necessary to maintain a leading position in the broad range of scientific and technical fields required for this mission, and maintains close interaction with scientific and technical personnel in universities and industry.

Specific major programs include: (1) the research, development, and test activities associated with the nuclear design aspects of all phases of the nuclear weapon life cycle, and associated national security related tasks; (2) inertial confinement fusion, especially the short wavelength driver approach, aimed initially at weapon physics understanding and eventually civil power; (3) magnetic mirror fusion; (4) biological, ecological, and atmospheric aspects of energy and weapon technologies; (5) atomic vapor laser isotope separations; (6) other energy research programs; and (7) support to the U.S. intelligence community, the Department of Defense, the Nuclear Regulatory Commission, and other Federal agencies.

LOS ALAMOS NATIONAL LABORATORY MISSION STATEMENT

The primary mission of the Los Alamos National Laboratory is to be a national resource of scientific, technical and engineering capabilities focused on execution of its primary national security mission. It undertakes those multidisciplinary fundamental and applied research and development activities necessary to maintain a leading position in the broad range of scientific and technical fields required for this mission, and maintains close interaction with scientific personnel in universities and industry.

To fulfill its mission, it focuses its scientific and technical efforts on: (1) research, development and test activities associated with the nuclear design aspects of all phases of the nuclear weapon life cycle; (2) associated national security related tasks, particularly in strategic defense technologies, gas laser inertial fusion, intelligence analysis, verfication and control technology, molecular laser isotope separation, nuclear materials safeguards and security, and development of advanced nuclear and non-nuclear weapon concepts; (3) advanced magnetic fusion concepts; (4) nuclear physics; (5) high and medium energy physics, particularly in studies employing the Los Alamos Meson Physics Facility; (6) heavy ion fusion; (7) life sciences and environment; (8) basic energy sciences; (9) base technology for nuclear, fossil, renewable and geothermal energy; (10) conservation; (11) materials science; (12) modern chemistry; (13) chemical analysis; (14) lasers and photochemistry; (15) technology for control or isolation of nuclear, toxic or hazardous wastes; and (16) other energy research programs and support to the Department of Defense and the Nuclear Regulatory Commission and other federal agencies.

OAK RIDGE NATIONAL LABORATORY MISSION STATEMENT

The primary mission of Oak Ridge National Laboratory is to carry out applied research and engineering in fusion, fission and other energy technologies, and scientific research in basic physical and life sciences. Oak Ridge designs and provides research facilities for the benefit of members of the scientific and technical community, and maintains close interaction with scientific personnel in universities and industry. An important part of Oak Ridge's mission is the manufacture and sale of radioactive and stable isotopes that are not available from the private sector.

To fulfill its mission, Oak Ridge focuses its scientific and technical efforts on: (1) magnetic fusion, with emphasis on applied plasma physics, experimental and design studies of confinement configurations, development of plasma heating and fueling systems, development of prototype superconducting confinement magnets, and testing of candidate first wall and blanket materials; (2) nuclear fission, focused on development of nuclear fuel reprocessing, materials testing and development for high-temperature gas-cooled and breeder reactors, and technologies for managing nuclear waste; (3) biological and environmental research, with emphasis on interaction of energy-related physical and chemical agents with living organisms; (4) fossil energy, focused on development of materials for fossil fuel applications, and on health and environmental effects of coal conversion systems; (5) conservation and renewal energy, with emphasis on generic research for materials and technology development for buildings; and (6) basic research in physical sciences, with emphasis in materials research on radiation effects, neutron scatting and photovoltaic conversion, in chemical sciences on aqueous solutions, and in nuclear physics on heavy ion reactions.

PACIFIC NORTHWEST LABORATORY MISSION STATEMENT

The primary mission of Pacific Northwest National Laboratory is to carry out applied research and engineering for special nuclear materials production, nuclear waste management, and energy technology development. Pacific Northwest capitalizes on its co-location with Battelle facilities to maintain close interaction with scientific and technical personnel in the private sector.

To fulfill its mission, Pacific Northwest focuses its scientific and technical efforts on: (1) nuclear waste management, with emphasis on monitored retrievable storage, commercial spent fuel, and waste treatment technologies; (2) nuclear materials production, with emphasis on technical support of the Hanford production complex; (3) nuclear reactor safety, focused on human safety analysis, environmental impact assessment, fuel performance, and biological effects of nuclear and non-nuclear emissions; and (4) energy technology development, with emphasis on solar conversion and energy storage.

SANDIA NATIONAL LABORATORIES MISSION STATEMENT

The primary mission of Sandia National Laboratories is to be a national resource of scientific, technical and engineering capabilities focused on execution of its primary national security mission. It undertakes those multidisciplinary fundamental and applied research and development activities necessary to maintain a leading position in the broad range of scientific and technical fields required for this mission, and maintains close interaction with scientific personnel in universities and industry.

To fulfill its mission, it focuses its scientific and technical efforts on: (1) research and development associated with weapon engineering for all phases of the nuclear weapon life cycle; (2) associated national security related tasks, particularly in nuclear materials safeguards and security, inertial confinement fusion, verification and control technology, defense waste management and development of advanced concepts, such as the Strategic Defense Initiative; (3) conservation and renewable energy, focused largely on solar energy; (4) nuclear energy, principally in waste management and reactor safety; (5) fossil energy, including combustion of fossil fuels and geotechnology research; (6) fusion energy, mainly in plasma/material interactions; and (7) other research and development programs in support of the Department of Defense and the Nuclear Regulatory Commission.

Guide to Energy R&D Programs for Universities & Other Research Groups

June 1984

U.S. Department of Energy
Office of Energy Research
Washington, D.C. 20585

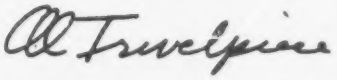
Foreword

The goal of national energy policy is to foster an adequate supply of energy at reasonable costs. The strategies for achieving this goal include the development and promotion of a balanced, mixed and diverse energy resource system. This balance and diversity is encouraged through the support of research and development by both the Government and private industry on new and alternative energy technologies to help ensure adequate future supplies of energy.

The Department of Energy (DOE) is the Federal Agency responsible for carrying out a comprehensive and balanced national energy program. A major part of this responsibility is the support of advanced scientific and technical research. This research serves two essential purposes. First, it advances the frontiers of scientific and engineering knowledge which, in turn, provides the underlying basis for future technological innovation. Second, it supports the development of new and alternative energy resources by providing the necessary scientific and technical basis for further development and ultimate commercialization by private industry. Within this context, DOE is specifically responsible for supporting basic research in the energy-related physical, life and environmental sciences; applied and proof-of-concept research in energy technology areas where the incentives for and the availability of private investment are severely limited or nonexistent; promoting energy conservation; carrying out essential nuclear defense-related activities; administering energy regulatory programs; collecting and analyzing energy information and data; and supporting fundamental research in the energy-related sciences.

Performers of DOE-sponsored research and development include industrial companies, Federal laboratories, universities and colleges. Participation by universities and colleges in the Department's energy research and development programs is particularly essential in that it constitutes a necessary national investment not only in advanced research, but also in the preparation and training of the next generation of the Nation's scientists and engineers. Universities are also a crucial link in the transfer of scientific and technical knowledge on energy to other users both in Government and in industry. Recognizing this, the Department is particularly interested in encouraging and supporting cooperative efforts in research and related manpower development involving universities, industry and the Federal laboratories.

We believe this guide will be of significant assistance to researchers in determining whether or not their research interests meet the needs and requirements of the Department of Energy. We would be most interested in comments and suggestions on how this guide may be improved as a resource for the scientific and technical community interested in DOE-sponsored programs.



Alvin W. Trivelpiece
Director, Office of
Energy Research

livestock, and forest production has shifted from the Northeast to other regions. The Northeast Regional Council submitted 10 priorities to the Joint Council, headed by basic research and scientific expertise development. Profitability in agriculture and farm financial and business management were the top two priorities of the Northeast Region Extension Directors.

North Central Region

More than 40 percent of the Nation's farm cash receipts are generated in this region. The region is an important producer of red meat, dairy products, food and feed grains, and oilseed crops. Major issues affecting this region are decline in farm profitability, soil erosion, competition for land use and resources, and export and commodity prices. The North Central Extension Directors placed farm financial and business management as their top priority, followed by profitability in agriculture. The North Central Agricultural Research Committee ranked biotechnology as the highest priority, followed by agricultural profitability.

Southern Region

Southern producers, like those in other U.S. regions, are faced with markedly lower profits. Soil erosion is a problem, and there is an urgent need to increase efficiency by focusing on plant and animal production systems. The Southern Regional Council submitted 13 priorities. The first was improved water management and water use efficiency; and second was improved animal health and reproduction. Extension Directors in the Southern Region gave profitability in agriculture and farm financial and business management their first and second rankings. The Southern Regional Research Committee placed the greatest emphasis on biotechnology, followed by soil and water management.

Western Region

The states in the Western Region have very diverse climates, topography, and agricultural commodity production. Water is a key to the West's economy. The Western Regional Council submitted 11 priorities for consideration by the Joint Council. Improving the use and conservation of water was the top priority of this Council, followed by product and market development. The Western Directors of Extension ranked agricultural profitability as their most urgent priority, followed by farm financial and business management.

Selecting the Top Priorities

After the Joint Council received the priority lists, the staff combined items covering similar areas. The consolidated list was first ranked in order of priority by Joint Council members individually. Subsequently, the Council met to discuss the proposals and select the five highest priorities for FY 1987.

Part I.
DOE Research and Development Programs

Introduction

The Department of Energy performs several roles in support of the overall national energy effort. These roles may be summarized as follows:

- Develop fundamental scientific and engineering knowledge related to long-range energy R&D needs.
- Carry out energy-related applied research and technology development programs in specific areas that involve large, unpredictable and long-term costs or payoffs and, therefore, attract little or no private sector funding.
- Manage programs and facilities for national defense in the areas of nuclear weapons, nuclear materials and naval reactors.
- Stimulate the development and utilization of a wide range of energy options including conservation and renewable and conventional resources.
- Develop and manage energy emergency preparedness policies and programs.

DOE Organization

The organization of the Department of Energy includes a central headquarters staff located in both Washington, D.C., and in Germantown, Maryland, and an extensive network of program dedicated facilities and laboratories. Responsibilities of the DOE Headquarters include overall program management, planning, scheduling, budgeting, resource allocation and maintaining close working relationships with other Federal agencies and the Congress. The current organizational structure of the Department is shown in the chart on the preceding page. Most of the major energy research and development programs are administered by program staff located in the central Headquarters organization; however, there are several more applied research programs that are managed by staff in the program field offices and facilities. The reader is advised to check the "Proposal Review Procedures" section at the beginning of each major program area discussion for guidance on this matter.
formal proposals. Some program offices use in-house staff to review proposals while others may extensively use scientists at DOE laboratories and field facilities. Some programs use special advisory committees and panels to review proposals; others will exclusively rely on external mail review of proposals. The program staff contacts listed in each section of the guide should be consulted on the procedures followed in reviewing proposals in each program. The interested researcher seeking preproposal guidance on research needs and opportunities should also recognize that, while the ultimate program management responsibility always rests with DOE headquarters, some of the day-to-day implementation decisions may be delegated to a DOE field facility. In such instances, effort should be made to identify and communicate with the appropriate project manager in the field.

Principal Staff Officers

The Secretary of Energy is the chief executive officer of the Department. The Secretary's principal staff consists of a Deputy Secretary, an Under Secretary, a General Counsel, an Assistant Secretary for Management and Administration, the Director of the Office of Energy Research, and Program Assistant Secretaries and Administrators responsible for oversight and management of major Departmental programs.

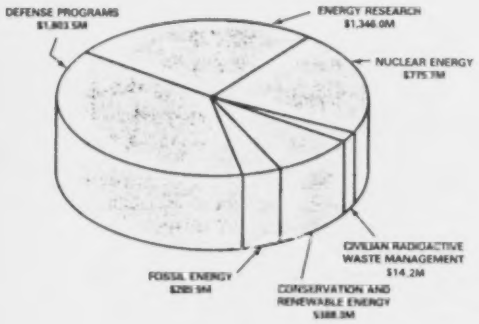
Information regarding the proposal review procedures used by each major program area is either included at the beginning of each program area discussion or is given in greater detail in the individual project description. It should be noted that there are differences among the DOE programs in the handling and review of preliminary and

Program objectives are cited for each technical program included in the guide together with a listing of problem areas requiring additional research and potential areas for new research initiatives. Summary budget data are provided to show the portion of funds for total research and development for a particular program area. The portion of the total program budget allocated for the support of research and development in universities is shown in Table I of the "DOE Budget Obligations" section.

A general point of contact is listed along with program-specific contacts to provide additional information. Telephone numbers for the points of contact listed in this guide may change from time to time. *Current DOE headquarters telephone numbers may be obtained by dialing the DOE locator; (202) 252-5000.*

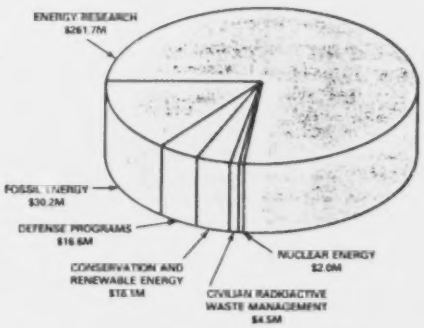
DOE Budget Obligations by Type of Procurement-FY 1984

TOTAL R&D BUDGET FOR FY 1984
($ IN MILLIONS)



TOTAL: $4,613.6 MILLION

DOE UNIVERSITY R&D FOR FY 1984
($ IN MILLIONS)



TOTAL: $331.1 MILLION

Budget Considerations

The figures above illustrate the total DOE R&D budget and highlight the estimated proportion of the budget being provided to universities for research and development initiatives. During FY 1983, an estimated $40 million was provided by the DOE National Laboratories on a subcontract basis for university research and development projects. In addition to this direct funding of university research by DOE programs, over $200 million of indirect support was provided to university faculty and students in FY 1983 through the Department's National Laboratories. (This total includes an estimate of the portion the operating costs of Laboratory research facilities when they are "used" by university scientists.)

A breakdown of funds for university research and development (direct awards only) by major program area is shown in Table I. The reader should be reminded, however, that these dollar figures are estimates only, and are subject to Congressional and programmatic changes which may occur at any time during the fiscal year.

Research Needs and Opportunities

The following section is devoted to a brief description of the major outlay programs of the Department of Energy and those technical programs included under each. These major areas are:

- Energy Research
- Conservation and Renewable Energy
- Defense Programs
- Fossil Energy
- Nuclear Energy
- Nuclear Waste Management (Commercial)

Other programs within the Department are not discussed in these descriptions because they support little, if any, R&D.

Also included are descriptions of DOE programs of special interest to the research community, including: the Energy Information Administration, the Office of Minority and Economic Impact, and the Office of Small and Disadvantaged Business Utilization. To assist the reader in determining field activity relationships, each major area discussed includes a brief section entitled "Field Elements."

Major R&D Programs

The major DOE research and technology development programs are organized under four Program Assistant Secretaries for Conservation and Renewable Energy (including solar and geothermal energy R&D), Fossil Energy, Nuclear Energy, Defense Programs, the Director for Civilian Radioactive Waste Management, and the Director of the Office of Energy Research (who is responsible for longer-range energy research, including general science related research). The Office of Energy Research has a major responsibility for the support of research involving universities.

The following pages include descriptions of each of the major R&D program areas in the Department and the Department's extensive national network of facilities and laboratories. It should be emphasized that many of these facilities and laboratories carry out research and related programs of direct benefit and assistance to university faculty and students including, but certainly not limited to, the operation of unique major research facilities and instruments such as high energy particle accelerators and synchroton radiation light sources. A summary of the major DOE field and laboratory network may be found in Parts II and III of this Guide.

Office of Energy Research

General Description

The Director of Energy Research is the principal advisor to the Secretary on DOE's physical research programs, the Department's overall energy research and development programs, environmental and health effects research, and university-based education/training activities. The Director also carries out additional duties assigned to the Office related to basic and advanced research, and the well-being and management of the non-weapons, major multiprogram laboratories under the jurisdiction of the Department.

The Office of Energy Research has also been assigned the administration and management responsibilities for the Small Business Innovation Research (SBIR) program of the Department. This is a new program developed to strengthen the role of small businesses in meeting Federal R&D needs and to stimulate technological/commercial innovation. Funds for the SBIR program are provided from all of DOE's major R&D program areas. A synopsis of the SBIR program and the other major programs of the Office of Energy Research is provided on the following pages.

Field Elements

Four multiprogram, six program dedicated facilities and eleven environmental laboratories are administratively assigned to the Office of Energy Research. Each of the four multiprogram laboratories (Argonne National Laboratory, Brookhaven National Laboratory, Oak Ridge National Laboratory, and the Lawrence Berkeley Laboratory) is briefly described in Part III of this guide. The program dedicated laboratories (the Ames Laboratory at Iowa State University, the Bates Linear Accelerator Facility at the Massachusetts Institute of Technology, the Fermi National Accelerator Laboratory, the Notre Dame Radiation Laboratory, the Princeton Plasma Physics Laboratory, and the Stanford Linear Accelerator Center) are summarized at the end of this Section. The multiprogram laboratories conduct significant research activities for other DOE programs and other Federal agencies, while the specialized and environmental laboratories are funded almost totally by a single program of the Office of Energy Research.

A summary of the proposal review procedures used by each research area within the Office of Energy Research is included in the individual project descriptions.

University Research Support Program

Program Objective

The Division of University and Industry Programs in the Office of Energy Research performs two functions of particular interest to the university community.

The Division is responsible for the administration of a number of special university-oriented research and manpower development programs such as the Laboratory Cooperative Program and the assessment of projected manpower requirements for future energy research/technology development programs. The Division also carries out responsibilities designed to help strengthen and improve the Department's overall relationships with the academic community.

The university-related programs supported by this office are summarized as follows:

- The University Laboratory-Cooperative Program includes a variety of activities that bring college and university faculty and students to DOE Laboratories and Energy Technology Centers to participate in ongoing research programs and intensive instructional sessions on energy-related topics. These activities take full advantage of the unique and specialized facilities and research instrumentation at the Laboratories. Additional information on this program may be obtained by contacting staff members at participating DOE National Laboratories. (See Reference 1)
- The University Reactor Fuel Assistance Program provides financial support to colleges/universities to maintain nuclear research and training reactors, and to promote reactor sharing among colleges and universities.
- The University Research Instrumentation Program—The principal objective of this program is to provide financial assistance on a competitive basis to university research groups for the purchase of sophisticated, state-of-the-art research instrumentation required for advanced energy research. A program solicitation is prepared and released annually describing the specific objectives and areas of emphases for the program. Instrumentation eligible for support under this program will cost about $100,000 and above. This program is an integral part of the overall Federal effort designed to help reduce the shortage of major research instrumentation available to university scientists.
- The Energy Education and Training Program—This program provides support for a small number of pre-college oriented activities principally involving secondary school science teachers and students. Included in this overall program is the Pre-Freshman Engineering Program (PREP) which partially supports university-based engineering enrichment activities for minority and women secondary school students. The goal of the PREP program is to encourage minority and women students to pursue engineering careers following graduation from high school. Typical activities in a PREP project include science and mathematics remedial instruction, field trips to engineering-related industries, group and individual class projects, computer orientation and other problem solving tasks. Another related program activity supported by the Energy Education and Training Program involves scientists at various DOE national laboratories conducting short courses and institutes on energy-related science and engineering for secondary school science teachers and students in nearby school districts.
- Used Energy-Related Equipment Program—The purpose of this program is to provide university scientists and engineers with laboratory-related scientific instrumentation which has been declared surplus by DOE National Laboratories. This instrumentation (generally smaller instruments such as microscopes, oscillographs, etc.) is made available on a "first come-first serve" basis to universities for use in energy-oriented research or educational programs. Proposals requesting such surplus equipment should be submitted by the interested institution to the DOE Operations Office responsible for the site where the specific equipment to be surplused is located. Reference 2 provides further information on the policy and procedures for this program.

Staff in the Division also provide general assistance to university researchers and administrators interested in learning more about potential DOE energy research opportunities/needs and in establishing contact with appropriate Departmental program managers. Information and materials on DOE energy research and technology development programs are available from staff in the Division along with information on potential research and manpower development opportunities available to university faculty and students through the Department's various National Laboratories.

Proposal Review Procedures

Unsolicited proposals submitted to the Division of University and Industry Programs are reviewed by both Division staff and by external peer reviewers, as appropriate.

The PREP and University Research Instrumentation programs are competitive programs with annual solicitations. Proposals submitted in response to these solicitations will be evaluated by panels of experts in the appropriate scientific and technical areas.

Basic Energy Sciences

Program Objectives

The Office of Basic Energy Sciences (BES) is responsible for long-range basic energy-related research and is charged with providing the fundamental scientific foundation on which the nation's future energy options depend. Research is sponsored in selected areas of the traditional scientific disciplines—the physical and biological sciences, geosciences, engineering, and mathematics. Research projects are selected on the basis of scientific merit, the possible relevance to meeting BES long-range research goals, and the contribution toward a balanced, responsive research program.

The knowledge that results from BES-sponsored research becomes a part of the body of information on which the applied technologies rest. Although research to broaden the technology base needed for identified energy options is extremely important, even more important is the need for basic research unfettered by preconceived notions of what technologies will be important several decades from now so that new, not yet identified options may emerge.

While the Office of Basic Energy Sciences assigns priorities to specific areas based on a judgment of their importance to the Department's mission, the detailed substance of the program is determined by the selection from among many unsolicited proposals of ideas from the university/scientific community. Since basic research is usually carried out within the framework of the scientific disciplines, the program is structured and managed mostly along disciplinary lines.

There are seven subprograms:

- Materials Sciences
- Chemical Sciences
- Nuclear Sciences
- Engineering, Mathematical and Geosciences
- Advanced Energy
- Biological Energy Research
- Carbon Dioxide Research

The titles are descriptive, but do not convey the range of subject matter covered. For example, Chemical Sciences includes research in atomic and molecular physics, nearly all aspects of chemistry, chemical instrumentation, and some chemical engineering. Coverage by the other subprograms is similarly broad.

There are currently more than 1,200 research projects funded by Basic Energy Sciences. The following table provides the subprogram budget breakdown:

Each of the subprograms in Basic Energy Sciences has selected technical areas that are to be emphasized. It would be impractical to list them here in any detail. Those interested in these specific details should contact the individuals listed under "Program Information Contacts."

Proposal Review Procedures

Unsolicited research proposals are first screened by program officials, and if appropriate, are evaluated by peer review. Successful proposers are awarded one-year or multi-year special research contracts or grants with renewals or incremental funding available, provided performance has been satisfactory. Minimal technical reporting requirements are imposed, basically those needed for decisions as to renewal or termination. A one-to-two year phase out period is normally granted to those finishing research projects, in order to bring the work to an orderly conclusion and to support graduate students finishing their thesis research. All results are expected to be published in the appropriate scientific and technical journals.

Equipment items can be purchased from contract funds, with the agreement of program officials and the authorization of the contracting officer. The program also operates a number of unique facilities, usually located at the national laboratories, which are available to the user community. These include neutron scattering diffraction facilities, electron microscopes,and the Combustion Research Facility at the Sandia National Laboratory at Livermore, the National Synchrotron Light Source at Brookhaven National Laboratory, and the Stanford Synchrotron Radiation Laboratory. For a description of the facilities and their availability, please see Reference 1.

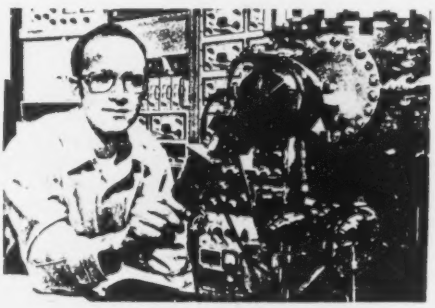
Materials Sciences

Research conducted under the Materials Sciences program is aimed at understanding materials properties and phenomena of importance to all energy systems. Materials often are the key limiting factor in the development of new systems, the performance of present systems, and the evolution of advanced concepts. In the Materials Sciences program, emphasis is placed on areas where problems are known to exist or are anticipated. Improved understanding of materials properties is sought in areas where significant improvements in performance and, therefore, economics depend on the selection of materials and design.

Some needs to which Materials Sciences research contributes include:

Budgetary Breakdown by Disciplinary Subprograms
(Operating Expenses)

	FY 1983 (Actual)	FY 1984 (Est.)
Materials Sciences	108.2	125.1
Chemical Sciences	70.0	75.5
Nuclear Sciences	30.6	37.9
Engineering, Mathematical and Geosciences	31.0	33.7
Advanced Energy Projects	8.3	9.1
Biological Energy Research	9.5	10.6
Carbon Dioxide Research	9.1	12.5



- Developing new or substitute materials;
- Tailoring materials to satisfy defined requirements;
- Predicting materials problems and service life;
- Improving the ability to successfully attack unforeseen materials problems in advanced energy systems; and
- Improving the theoretical and experimental capability to analyze the fundamental structure of materials.

BES's Materials Sciences subprogram provides about one-third of the total federal funding for basic materials research. Materials Sciences emphasizes selected generic areas of fundamental importance and areas where problems are known to exist or are anticipated. Some research is directed at a single energy technology (e.g., photovoltaic materials for solar energy conversion); some research has applicability to many technologies simultaneously (e.g., embrittlement of structural materials in the presence of hydrogen); and still other research has more fundamental implications underpinning all materials research (e.g., mechanisms of atomic transport in solids). The research is conducted in a variety of institutions—DOE laboratories, universities, and, to a lesser extent, industrial installations—and uses the talents of metallurgists, ceramicists, solid-state physicists, and materials chemists.

Chemical Sciences

Under the Chemical Sciences program, research is conducted in areas of chemistry, chemical engineering and atomic physics—both to provide a basis for the solution of current energy technology problems and to open new concepts for future development. The data and understanding that this program produces are of the kinds that can help make economically viable such newly developing energy technologies as coal liquefaction, or can help make possible other technologies such as fuel-making solar cells.

Phenomena and processes likely to be important to energy technologists are emphasized in the formulation of the program. Research in some areas, such as the chemical effects of catalysts, may lead to discoveries that can be quickly exploited by industrial process designers; whereas in other areas such as water-splitting photochemistry to produce hydrogen, research may not be used for a number of years. Still other research areas, such as studies of radiation emitted by ions moving very fast through crystal foils, produce data for use in developing new energy technologies.

The Chemical Sciences subprogram includes research in the fields of photochemistry, coal chemistry, catalysis, atomic physics of highly charged ions, chemistry basic to nuclear waste separation, biomass conversion, recovery of valuable metals from low-grade resources, efficient and clean combustion of various fuels, and detection and measurement of harmful by-products of energy processes. Equally important is the fundamental research into chemical and physical phenomena which has no immediately identifiable related technology. A typical example of such efforts is the study of laser-induced excited states of molecules. Disciplinary areas covered by Chemical Sciences work include physical, organic, and inorganic chemistry; chemical physics; radiation chemistry; thermodynamics; thermophysics; and analytical chemistry.

Nuclear Sciences

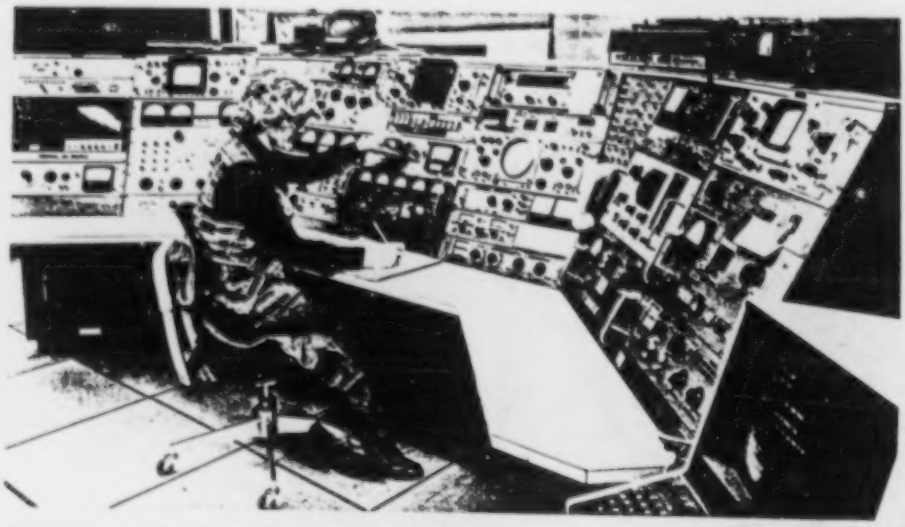
The Nuclear Sciences subprogram involves five distinct activities:

- Measure, compile, and evaluate nuclear data for fission and fusion energy technologies;
- Improve knowledge of the chemical and physical properties of the actinide elements;
- Assure the availability for research of isotopically enriched samples of the elements;
- Operate the Stanford Synchrotron Radiation Laboratory;
- Develop heavy ion accelerator technology (the Heavy Ion Fusion program).

The fission and fusion energy technologies require nuclear data for optimization of reactor design, analysis of operations and safety of reactor systems, and management of spent fuel materials. The nuclear data activity provides a broad base of data in support of these technologies.

The compilation and evaluation effort is concerned with establishing a data base for neutron-induced nuclear reactions and also with maintaining the Evaluated Nuclear Structure Data File (ENSDF), which encompasses all the information produced worldwide on the level structure and decay properties of nuclei. This effort is centered around the National Nuclear Data Center (NNDC) at Brookhaven National Laboratory, which coordinates a network of scientists performing compilation and evaluation for ENSDF and also coordinates U.S. work with the International Atomic Energy Agency. Nuclear data measurement effort centers around the Oak Ridge Electron Linear Accelerator for measurement of neutron cross sections over a wide range of energies. Several small university groups and the National Bureau of Standards collaborate in these activities.

The nuclear energy and technology programs of DOE need specific information and data on the behavior of actinides in fuel processing streams, in nuclear waste hosts materials, and in the environment. Heavy element chemistry research helps meet their needs as well as contributing to an understanding of the fundamental chemical and physical properties and behavior of matter. These broadly based studies of the actinide elements include behavior in aqueous and nonaqueous solutions, photochemistry, chemical reactivity, spectroscopy, and chemical physics. The study of actinide chemistry is largely limited to the national laboratories since high



levels of radioactivity are involved, but some tracer work is done at universities. At the national laboratories, opportunities for visiting scientists from university and foreign labs to pursue collaborative research with the U.S. investigators are provided.

Nuclear Sciences also supports the electromagnetic separation of stable isotopes for a Research Materials Collection of samples that are loaned out for nondestructive research in DOE energy technology programs. In addition to its research and information-gathering activities, Nuclear Sciences is responsible for distributing the stable isotopes and the rare, heavy radioactive isotopes it produces for use in research, medicine, and industry. These efforts constitute the western world's only source of isotopic research samples in significant quantities, and these materials are sold or loaned to institutions throughout the world.

Responsibility for operating the Stanford Synchrotron Radiation Laboratory (SSRL) has recently been transferred to BES from the National Science Foundation. The SSRL, which shares the Stanford Positron Electron Asymmetric Ring with the high-energy physics program, is an important research facility. At present, it is heavily oversubscribed by the solid-state, chemical, and biomedical research communities for its high-intensity photons in the ultra-violet and X-ray regions of energy. This is one of two major BES facilities where research of this kind is made possible.

The Heavy Ion Fusion Accelerator Research (HIFAR) program is a new program under the energy activities within the Office of Energy Research. The program was previously supported by the Office of Inertial Fusion within Defense Programs. The goal of the HIFAR program is to develop heavy ion accelerator technology and perform appropriate ion beam experiments to the point where an adequate data base exists for evaluation of heavy ion inertial fusion drivers for use in civilian power applications. A program plan has been formulated based on the development of high current, multi-beam induction linacs to achieve the requisite peak beam power. Research includes advanced accelerator design, limits on beam current, beam focusing and stability, and preservation of required beam quality. Currently the effort is concentrated at the Lawrence Berkeley Laboratory and the Los Alamos National Laboratory.

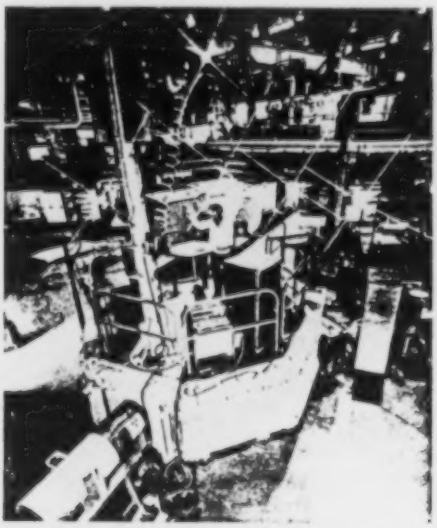
Engineering, Mathematical and Geosciences

The Engineering, Mathematical and Geosciences program funds fundamental research in a variety of disciplines important to meeting our Nation's energy needs. The program is carried out under three distinct activities: Engineering Research (mechanical, electrical and structural engineering), Applied Mathematical Sciences (mathematics, statistics and computer science), and Geosciences (geophysics geochemistry and geology).

The *Engineering Research Program* was initiated in 1979. The broad objectives of this program are to add to the store of fundamental knowledge for advancing energy-related engineering practices, to stimulate new engineering approaches to solving the Nation's energy problems, and to enhance the intellectual base for future energy-related engineering developments.

At present, three research areas are receiving high priority:

- Mechanical sciences-including tribology (the basic nature of friction-reduction phenomena), heat transfer, and solid mechanics (continuum mechanics and engineering aspects of crack propagation);
- Systems sciences-including process control, instrumentations, and scale-up of process plants;
- Engineering analysis-including nonlinear dynamics, thermophysical properties of fluids, and engineering combustion.



Engineering research also includes work on instrumentation for measuring basic engineering quantities—temperature, pressure, flow rates, and phase-under extreme conditions of temperature or pressure and efforts to model complex systems to develop predictive capabilities for the scale-up of pilot process plants.

The BES activity in *Applied Mathematical Sciences* supports approximately 200 mathematicians, statisticians, and computer scientists working on fundamental problems in the development of mathematical models of energy systems. The work is carried out at 30 universities and 10 national laboratories. In areas such as magnetic fusion, nuclear reactors, weapons design, and combustion processes, where experimental tests are difficult, expensive or even impossible, mathematical models provide the best methods of studying the underlying physical processes. The mathematics program emphasizes three aspects of the modeling process:

- Analytic and computational techniques for formulating and implementing models of energy systems from first principles;
- Statistical and computer science techniques for manipulating and analyzing large data bases associated with these models; and the
- Development of algorithms, languages, and architectures for future generations of computers that will be capable of solving more realistic models.

The most promising parallel computer architectures are being explored, concentrating on techniques for using hundreds or thousands of inexpensive microcomputers in parallel to solve complex systems of equations at rates ten to a hundred times faster than the best computer available today. A coordinated effort among university, national laboratory, and industry researchers is under way.

The nonlinear dynamics research promises to aid in understanding the nature of turbulence and chaotic motion, which governs reaction rates in combustion processes and plasmas, and coolant flow in reactors.

The objective of the *Geosciences* program is to develop a quantitative, predictive understanding of the energy-related aspects of geological, geophysical, and geochemical processes both in the earth and at the solar-terrestrial interface.

The Geosciences program is presently emphasizing (1) long-range research on the geological isolation of nuclear waste, (2) studies in organic geochemistry relating to fossil fuel recovery and the disposition of energy-related chemical waste, and (3) studies of the magma-hydrothermal part of the interagency Continental Scientific Drilling Program.

The effort in nuclear waste isolation addresses unresolved problems with second- and third-generation repositories, such as: migration of nuclear wastes; interactions among the waste container, rock, and fluids in the rock; and concentrations, diffusion rates, and element migration of nuclear wastes from a disposal site into its surroundings.

The organic geochemical processes of migration, physical changes, and maturation of fossil energy resources are also being studied. Such knowledge is essential if fossil fuels are to be effectively exploited and is required for dealing with the problems of organic wastes.

Advanced Energy Projects

The objective of the Advanced Energy Projects (AEP) subprogram is to explore the feasibility of novel energy-related concepts evolving from basic research which are at an early stage of scientific definition and, therefore, would not be of interest to technology programs. Advanced Energy Projects is an interdisciplinary program whose projects cover a broad technological spectrum. To qualify for AEP support, such concepts, even though they involve a high degree of risk, must have the potential for an eventual high payoff. Advanced Energy Projects also sponsors exploratory research on concepts that do not fit easily into the existing DOE program structure. An area of major attention is the transfer of successful projects to technology programs; a number of such transfers have already been made.

A relatively new BES subprogram, Advanced Energy Projects supports individual projects for a limited time only, with the goal of supporting about 20 new projects each year. It differs from other subprograms in that it does not fund ongoing, evolutionary research. After a period of concentrated effort, typically about 3 years, the concept is expected to have proved itself, and in which case the basic research phase is completed and the project can be transferred to a technology program. If a successful conclusion to the research is not foreseeable, the project is dropped. Projects are selected from unsolicited proposals received from researchers at universities, industrial laboratories (especially small R&D companies), and national laboratories. Currently, 36 projects are being supported; this allows a turnover rate of about 12 projects per year.

Biological Energy Research

The principal objective of Biological Energy Research is to provide basic information and conceptual

understanding in microbiological and botanical sciences for DOE's efforts in biomass production of fuels and chemicals, microbiological transformation of organic materials for conservation, and biological systems for resource recovery. The research is aimed at enhancing biomass productivity, converting biomass and other organic materials into fuel and chemicals by novel and improved methods of fermentation and developing biosystems capable of saving money.

The Biological Energy Research subprogram focuses on understanding the limits of biomass productivity in green plants, how plants adapt to suboptimal conditions of growth, such as those encountered in marginal lands and waters, and the mechanisms of microbial conversion of various biomass forms. In particular, the biochemical pathways of degradation of abundant materials such as cellulose, hemicelluloses, lignins, and the conversion of these materials to fuels or chemicals are studied.

Microorganisms that grow in the absence of oxygen and are able to carry out fermentation with high efficiency are of special interest, as are thermophillic microorganisms, which have optimal growth and conversion rates at high temperatures. An integral part of the subprogram information that may ultimately be used to produce new or improved microorganisms and plants to facilitate the production of fuels or petroleum-conserving chemicals or to yield biotechnologies capable of conserving energy.

This research into the physiology, biochemistry, and genetics of microorganisms and plants is carried out primarily at the universities.

Carbon Dioxide Research

The objective of the Carbon Dioxide Research subprogram is to improve scientific understanding of possible CO_2 sources and sinks, CO_2-induced climate modifications, and direct fertilization effects of CO_2 on vegetation. The global CO_2 content of the atmosphere has increased in recent history and continues to rise at a rate of about 1.5 parts per million per year. The effects of increased CO_2 in the atmosphere are uncertain. Scientists agree, however, that it can cause global climate changes involving temperature, precipitation, and wind circulation and that it may create a "fertilizer effect," which would increase crop yield and result in greater storage of fossil-fuel CO_2 by forests.

Carbon Dioxide Research aims to establish "knowns and unknowns," reduce and specify uncertainties, increase data collection, and improve measurements and models directed at answering specific questions about the sources and sinks of CO_2 climate, and other possible effects.

Much of the current research is focused on defining and measuring fluxes of CO_2 among major sources and sinks of the carbon cycle. Research efforts also include estimates of global and regional changes in temperature and precipitation aimed at identifying which climate changes result directly from the effects of CO_2 (as differentiated from the many other factors that could have been involved). General circulation models are being used to determine how an atmospheric CO_2-induced climate change may relate to the nonatmospheric components of the climate system, such as oceans, land, and the cryosphere. Preliminary results of studies with nonatmospheric-ocean models suggest that effects may be delayed a decade or more by the thermal inertia of the oceans. The photosynthesis, physiological, and water use of plants and trees are being studied to provide a basis for predicting the responses of vegetation to rising atmospheric CO_2.

Health and Environmental Research

Program Objective

The mission of the Office of Health and Environmental Research is to conduct an authoritative and comprehensive research program to identify, analyze and reduce those health and environmental uncertainties which could unnecessarily impede the safe and economical implementation of U.S. energy policy. A second mission is to conduct a research and development program on the applications of nuclear technology to the diagnosis and treatment of human disease.

This program is the only interdisciplinary research effort in the Federal government specifically devoted to the broad range of long-term energy-related health and environmental issues we are likely to face in expanding existing energy technologies or deploying new ones. The goal is to identify before a technology is locked into place, the long-term effects, if any, on human and environment health.

Research will be supported which will help identify and characterize potentially hazardous energy-related agents; understand their transport, conversion and fate in the environment; determine their ecological impact and pathways to humans; and define their potential effects on human health via direct observation and through studies with experimental animal, cellular and molecular systems. Research will also be supported to elucidate the structure, function and interrelationships of key components of living organisms in order to better understand the basis for susceptibility of critical life processes to energy-related agents. Medically useful applications for radioactive and stable isotopes, radiation beams and associated instrumentation will also be supported.

Health Effects Research

This program supports a coordinated research effort designed to yield experimental health effects data of the type needed to predict long-term health impacts that may be associated with developing energy technologies. A comprehensive experimental program of health research is necessary because of severe and unavoidable limitations that inevitably complicate the acquisition and interpretation of health data on human populations exposed to environmental agents.

The program is primarily concerned with evaluating the delayed types of health effects—tumors, heritable defects, developmental effects, and damage to body systems (organs)—that are caused by chronic low-level exposure to energy-related physical and chemical agents. The research utilizes molecular, cellular, and animal test systems to obtain quantitative data on dose-response relationships and to develop an understanding of species differences in sensitivity. Since credible extrapolation of such data to man requires a knowledge of mechanisms underlying the induction of adverse effects in different species and since the production of delayed effects is not clearly understood, extensive use is made of generic and basic research to provide experimental systems, techniques, and insights having the broadest application to health-risk prediction. Included is the development of improved biological test systems and improved techniques for the extrapolation of experimental data to man.

Health effects research cuts across virtually all of the energy technologies. Areas of ongoing research include those that address health effects associated with ionizing radiation, d-c magnetic fields, and a variety of energy-related chemicals including indoor air pollutants, polycyclic aromatic hydrocarbons and related compounds

associated with synfuel production. Extensive research is conducted to elucidate mechanisms of carcinogenesis, mutagenesis, metabolism of energy-related chemicals, and mechanisms of DNA repair. Categories or research opportunity include:

- Carcinogenesis—Both established and developing energy technologies produce or involve physical and/or chemical agents that can cause human cancer. Carcinogenesis research emphasizes evaluation of the tumorigenicity of such agents, detection and characterization of carcinogens, elucidation of pathways of carcinogen metabolism, development of sensitive chemical/biological indicators of turmorigenesis, investigations to correlate exposure conditions (carcinogen dose) with tumor incidence in animal populations, and elucidation of mechanisms of carcinogenesis. Because tumorigenesis is a complex process that may include discrete initiation and promotion steps, research on cancer induction often involves the study of complex interactions among different causative agents. Emphasis is also being given to research on the ultimate free radicals and other oxidizing species that play a role in both chemical and radiation carcinogenesis, and on body defense mechanisms against harmful oxidizing species.
- Mutagenesis—Alteration of genetic material by physical and chemical agents may produce heritable defects as a result of mutations in reproductive cells. Mutations in somatic cells and alteration of chromosome structure may result in cell modifications leading to cancer or other health effects. The mutagenesis research program emphasizes investigations of the mutagenic potential of energy-related physical and chemical agents; metabolism of chemical agents in target cells; correlation of mutation frequency with level of exposure to a mutagen; evaluation of health consequences that mutations may produce at the population level; measurement of DNA damage such as adduct formation; and elucidation of mechanisms of mutagenesis including the relationship of mutagenesis to tumor induction. Cytogenetic effects (chromosomal modifications) are also studied in detail as is the relationship of mutagenesis to cancer induction.
- Systems Damage—Many hazardous environmental agents manifest their toxic potential by imparing one of the body's functional systems. Such effects—particularly delayed impairment of the respiratory, immune, nervous, reproductive, and blood-forming systems or the developing embryo/fetal system—may lead to chronic disease with attendant health costs. The major efforts in this research area include the identification of early indicators of biological damage, interspecies comparison of major functional systems and their sensitivity to environmental agents, development of improved biological test systems, and conduct of dose-response studies that support risk estimates for man.
- General Life Sciences—This program is focused on long-term, basic research with the aim of providing the mechanistic and conceptual foundation that is needed to understand how physical and chemical agents interfere with life processes. Emphasis is directed to molecular and cellular studies that provide a basis for studying and understanding how environmental agents interact with key cell components to induce undesirable health effects. Included is research on *biophysics* (structure of macromolecules and organelles), *genetics* (including DNA damage and repair), and *cell biology* (cell growth, cell differentiation, cell regulation, and enzymology).

Human Health and Assessments

The Human Health and Assessment Division supports research to provide information on: the response of humans and human populations to toxicants and the feasibility of using nuclear technologies in medicine. The Division also supports analyses of the potential health and environmental consequences of emerging energy technologies.

- Human Health Research—This program is concerned with adverse effects on human health resulting from exposure to chemical, physical and biological factors associated with energy generation. To determine the nature and the extent of energy related health effects, research is conducted on populations and individuals that have been accidentally or occupationally exposed. Research in this program also includes the development of methods for the detection, prevention, and treatment of the effects of occupational or accidental exposure to hazardous agents associated with energy activities.
- Medical Applications of Nuclear Technology—In this program research is conducted on: improved methods of producing nuclides of medical interest; new radiopharmaceutical agents; improved instrumentation for measurement of nuclides; and clinical trials of promising new medical procedures using both stable and radioactive nuclides. Research is also conducted to determine the feasibility of using other nuclear technologies in medicine including: synchrotron light; neutron capture, heavy particle beams and shaped radio-frequency fields.
- Health and Environmental Risk Analysis Program—This program supports analyses to determine current uncertainty regarding the nature and magnitude of the potential health and environmental impacts of emerging energy technologies, the potential impacts of toxicants common to several technologies, and research to improve risk-analytic methodologies.

Physical and Technological Research

This subprogram is the physical sciences component of the Health and Environmental Research program. It addresses a broad range of fundamental and applied activities. Many of the projects are interactive with the biological and ecological components of the office. Other projects involve development of experimental techniques or advanced measurement instrumentation. The major areas addressed are: the physical and chemical characterization of products and effluents of new energy technologies; the transport and transformation of pollutants in the atmosphere, including climate/energy system interactions; measurement science; health and safety; and, the fundamental mechanisms of pollutant interaction with environmental and biological systems. Categories of research opportunity include:

- Analytical Characterization—The distribution, concentration and the physical, chemical and radiological properties of emissions and effluents

associated with energy-technology processes are determined. Included are field sampling/measurement and laboratory studies to provide detailed information on the chemical and physical properties of collected materials.

- Atmospheric Transport and Transformation—This category includes research to develop an improved understanding of meteorological, chemical, and physical processes that influence the transport, transformation, and fate of gaseous and particulate species emitted into the atmosphere. Improved atmospheric dispersion models are developed and validated through field experimentation. Climate research improves techniques to forecast climate impacts on energy systems.
- Measurement Science—New concepts and improved measurement systems required to address environmental, health, and safety concerns related to energy production are investigated. Research covers a broad scope of activities ranging from the basic-science of measurements to construction and evaluation of prototype instrumentation systems.
- Health Protection and Safety Research—New and improved methods, techniques, and procedures for industrial hygiene and radiation health-protection applications are developed. Research activities cover development of personnel contamination assessment techniques, as well as new approaches for determination of exposure to chemical and radiation pollutants.
- Mechanisms of Pollutant Interactions—Research into the fundamental mechanisms by which physical and chemical pollutants interact with biological and environmental systems is pursued. This includes studies of mechanisms by which atmospheric pollutants react witheach other and with natural environmental constituents; and the mechanisms by which the energy of radiation is converted into chemical species that are biologically active. Studies are experimental and theoretical, with computational modeling support.

Ecological Research

The ecological research program provides the environmental information needed to satisfy energy-use demands in a cost-effective, environmentally safe manner for appropriate siting, operation, and disposal of materials from energy activities. To obtain this information base, comprehensive research in terrestrial and aquatic systems is conducted in different climatic regions of the United States and in offshore regions along the eastern and western United States on mechanisms which control and influence total ecosystems. The research is carried out by integrating all aspects of the physical and biological sciences. This multidisciplinary program covers fields of soil science, plant science, animal biology, chemistry, geology and freshwater/marine sciences.

Research includes defining the transport and transformation of energy byproducts in terrestrial and marine systems, and identifying the major routes and rates of transfer of these byproducts through physical and biological pathways to human exposure. Natural and energy-related stresses are studied from the subcellular level to the community level of ecosystems to determine the rate and mechanisms by which populations and ecosystems disturbed by energy activities adapt or react to these stresses. Categories of research opportunity include:

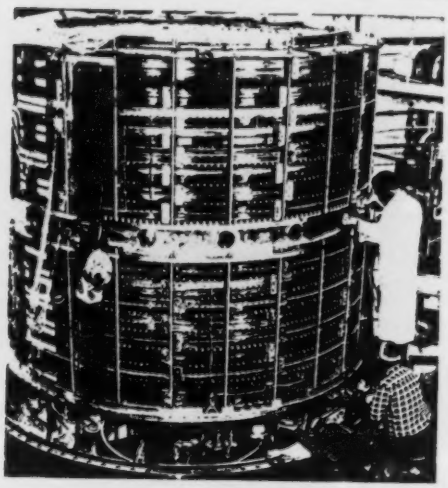
- Cycling of natural and energy materials which includes mobilization and movement of trace elements and compounds though water bodies, soils, sediments, plants and animals. Research on cycling of energy introduced substances is coupled to research on cycling of normally required nutrients to permit most appropriate cost effective measures to be developed for redistribution and control of energy material in the environment.
- Biologic responses derived from community structure, population dynamics and physiological ecology research. Knowledge on accommodation by plants and animals to natural stresses is used to allow energy-related activity to expand while taking into consideration limits of stress of the ecosystem. Natural successional processes are studied to determine if disturbed land is best left to natural revegetation or whether through habitat manipulation rehabilitation can be speeded up or enhanced. Research is carried out on metabolic processes which accumulate exposure levels that will allow ecosystems to exist without serious adverse impacts.
- Theoretical and statistical research to develop innovative theoretical approaches and sound statistical techniques that are applicable to ecological research in terrestrial, freshwater and marine environments.

Proposal Review Procedures

Unsolicited research proposals should be preceded by an informal preproposal that briefly describes the research project and the proposed level of funding. This need not exceed two or three pages. Preproposals are reviewed by OHER staff scientists to determine whether the proposed project falls within OHER's area of concern, and is of sufficient importance to justify preparation of a formal proposal. Generally a decision for this stage is made within a few weeks. If a formal submission is warranted, a copy of the pamphlet DOE/MA-0095 "Guide for the Submission of Unsolicited Proposals" will be provided.

The formal research proposal, after initial screening, is assigned to the appropriate OHER program division and a staff scientist designated to develop the formal evaluation and recommendation for action. All formal submissions are subjected to external peer review, generally involving three or more experts from the scientific community. The proposal and external reviews are then evaluated by a team of four or five technical staff drawn from the OHER professional staff of more than 30 scientists covering a diversity of biomedical and environmental disciplines. With the completion of this review step, the designated technical representative presents a summary of this proposal to the OHER Research Committee, (consisting of the technical staff from all program areas) for discussion and a formal recommendation for to the Associate Director for Health and Environmental Research for approval or rejection.

In selecting projects for support, OHER emphasizes its scientific merit (as it relates to energy or proposes to contribute knowledge to the field), the background and experience of the principal investigator, and the available facilities for the proposed work. Initiation of a contract from proposals found acceptable depends on the availablity



of funds and the importance of the proposed work in relation to other approved studies awaiting funding.

A period of three to six months may elapse before the proposal review is complete and a decision is reached by OHER. Receipt of the proposal will be acknowledged, and the applicant will be notified when a decision is reached with respect to the proposed work. If the proposal is approved, the applicant will be advised that, subject to the availability of funds, negotiation of an agreement or contract will be carried out by the designated DOE field office. DOE assumes no financial obligation until an agreement or contract has been executed.

High Energy Physics

Program Structure

The High Energy Physics Program is a basic research program which develops new fundamental knowledge and advanced technology of great value to energy programs. Its primary motivation is to understand the fundamental nature of matter and energy and the basic forces that govern their transformations. DOE provides about 90 percent of the Federal support, with the National Science Foundation providing the remainder. The central goal of these efforts is to achieve a comprehensive theoretical and experimental understanding of the fundamental constituents of matter and energy, the basic forces that govern their interactions, and the transformation of matter and energy in the most elemental level.

University research groups perform approximately 75 percent of the experiments scheduled at the three DOE high energy accelerators—Brookhaven National Laboratory, Fermi National Accelerator Laboratory, and Stanford Linear Accelerator Center. These laboratories are managed by universities or consortia of universities to provide unique and complementary capabilities in colliding beam facilities and fixed target accelerator systems which are vital to the frontier research program in high energy physics. University research, whether experimental or theoretical, is usually jointly funded by DOE and the home institution. For further information regarding laboratory facilities, see Reference 1.

Program Objectives

- Identify the ultimate constituents and structure of matter and energy;
- Understand the basic forces in nature which govern all interactions of matter and energy;
- Seek and discover new physical phenomena using high energy subnuclear particle interactions;
- Pursue advanced concepts and technology development;
- Maintain the United States program in a world leadership position; and
- Be alert to opportunities for the transfer of new technology developments and breakthroughs in high energy physics to energy development programs.

Long Range Planning for High Energy Physics

A typical experiment in high energy physics requires three-to-five years from design of apparatus to publication of results, while construction of a new accelerator facility usually consumes eight-to-ten years from conception to first beam operation. In cooperation with the High Energy Physics Advisory Panel and the National Science Foundation, the DOE High Energy Physics Program frequently updates its long-term strategy and plans for fulfilling the future needs of a strong and innovative research base. Strategy considerations include: the construction of specific new accelerator facilities as required for advances in research; effective operation of existing facilities; maintaining a strong university base; advanced technology development; funding for outstanding junior investigators; effective budget stability; and international collaboration for selected endeavors. The role of university scientists in determining and implementing long-range goals is important and pivotal

to all aspects of the program. The Outstanding Junior Investigator Awards have enabled creative young tenure-track scientists at the universities to launch independent research projects. Through the combined efforts of DOE program directors, advisory committees, special panels, university research offices and consultant contracts, colleges and universities have participated directly in DOE's attempts to seek the highest level of competence available for research requiring unique skills and expertise.

Proposal Review Procedures

Unsolicited proposals from universities to DOE for research support are analyzed by the High Energy Physics Program staff and undergo external peer review on an individual basis. Occasionally, competing proposals are also reviewed by special ad-hoc panels. Independently, experimental research proposals are submitted to national accelerator laboratories for review by a laboratory program advisory committee consisting of a panel of university and laboratory experts from across the nation. The program advisory committee advises the laboratory management on the scientific priority and merit of proposed research. The final decision to make accelerator facilities available for a particular experiment rests with the laboratory management. Successful research proposals for DOE support usually receive one-year contracts with provisions for review and renewal on an annual basis. Research results are expected to be published in appropriate journals. In addition to contributions of university research groups in forefront basic investigations, the universities provide fertile training grounds for the influx of new talent, which is essential to maintain the greatest vitality and creativity of the High Energy Physics program.

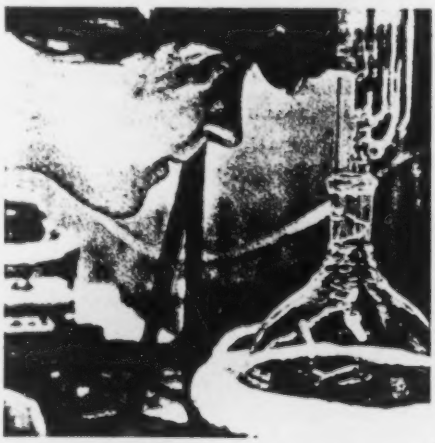
Magnetic Fusion Energy

Program Objectives

The DOE Fusion program consists of two activities—the unclassified magnetic fusion energy program, which is assigned to the Office of Energy Research, and discussed here, and the partially classified laser fusion program cited under Defense Programs.

The primary goal of the Magnetic Fusion Program is to develop the technology for safe, economic and environmentally acceptable use of fusion power for the generation of electricity. A secondary goal is to develop and evaluate other applications of the fusion process, including: the production of fissile material, synthetic fuels and industrial process heat. To achieve these goals, the program has established several objectives which are:

- To develop, through definitive experimental tests of key physics questions, the strong scientific base necessary for the design of a fusion engineering test facility;
- To complete the construction and initiate the operation of major physics scaling experiments including the Tokamak Fusion Test Reactor and the Mirror Fusion Test Facility;
- To select tests and provide an assessment of alternative fusion concepts that could potentially lead to more economical and commercially practical fusion reactor systems;
- To provide the base engineering and technology developments needed to support the operation of current and next generation plasma experiments;
- To complete reactor studies of the most promising confinement concepts in order to provide a focus for the physics and technology programs; and
- To establish a strong technology base in materials, reactor components and systems which will permit an evaluation of various approaches to fusion on the basis of technology requirements, economic objectives and environment/safety constraints.



Problem Areas Requiring Additional Research

- Physics of plasma heating and confinement;
- Plasma diagnostics;
- Atomic physics of plasma impurities;
- Improved materials for fusion applications; and
- Radiation materials damage.

Potential Areas for New Research Initiatives

- New fusion concepts and improvements to existing concepts;
- Plasma-surface interactions; and
- Modeling of engineering components.

Proposal Review Procedure
Solicited or unsolicited proposals are subjected to a technical peer review process. Acceptable proposals must provide for technical assessments of long-range, high-risk and high potential payoff research in energy technologies. Proposals for hardware development, development of models or algorithm tools, or experimental efforts, are not acceptable by the office. Proposals will be judged on the basis of their novelty, appropriateness to the Department of Energy's priorities, potential for useful data generation, expected quality of efforts, cost and availability of funds.

Nuclear Physics

Program Objectives
The DOE Nuclear Physics Program is the major Federal research effort concerned with advanced experimental and theoretical studies of the interactions, structure, and other fundamental characteristics of atomic nuclei. Its four major components are: Medium Energy Nuclear Physics, Heavy Ion Nuclear Physics, Low Energy Nuclear Physics, and Nuclear Theory. Medium Energy, Heavy Ion, and Low Energy Nuclear Physics are experimental efforts heavily dependent upon the existence and the effective operation of major accelerator facilities. Seven of these accelerators are operated as national facilities, where beam time is made available to the Nation's scientists on the basis of scientific merit and technical feasibility of proposals submitted. The national facilities are: the Clinton P. Anderson Meson Physics Facility at the Los Alamos National Laboratory; the William H. Bates Linear Accelerator at the Massachusetts Institute of Technology; the SuperHILAC/Bevalac at the Lawrence Berkeley Laboratory; the 88-Inch Cyclotron at the Lawrence Berkeley Laboratory; the Tandem/Linac Facility at the Argonne National Laboratory; the Holifield Heavy Ion Research Facility at the Oak Ridge National Laboratory; and the Double MP tandem van de Graaff facility at the Brookhaven National Laboratory. Each of these national facilities, as well as smaller accelerators at the University of Washington, Duke University, Texas A&M University and Yale University, accommodates major university-based user group research programs.

Major Objectives
- To describe quantitatively the behavior and structure of complex nuclei in terms of fundamental interactions;
- To use nuclei as a laboratory for the study of fundamental forces in nature;
- To develop phenomenological understandings in those cases where the nuclear system is too complex to be treated in terms of fundamental forces;
- To advance research capability by developing new facilities, improving beams available to existing facilities and equipping experimental areas with advanced instrumentation;
- To identify practical applications resulting from nuclear research studies and to transfer the results to the appropriate scientific discipline or technology; and
- To maintain a position of leadership in nuclear research for the United States.

Long Range Planning for Nuclear Physics
In cooperation with the Department of Energy and the National Science Foundation, the DOE/NSF Nuclear Science Advisory Committee has developed a long-range national plan for basic nuclear research. The plan recognizes the central importance of accelerator facilities and related instrumentation. It specifically calls for a balanced mixture of new facility construction and upgrading of existing facilities in order that major scientific questions may be attacked with adequate tools and in order that America's position of leadership in nuclear research may be maintained. However, the plan also clearly recognizes that our greatest asset is the creativity and innovativeness of American scientists. The role of university-based scientists is of central importance to this endeavor; both for the intellectual and other resources they bring to bear on today's research programs and for providing a fertile training ground for creative and innovative scientists of the future.

Proposal Review Procedures
A typical user group plans experiments at the home institution, executes and partially analyzes experiments at the national facility, and completes the analyses and publication of results at the home institution. The DOE Nuclear Physics program is the major Federal supporter of such university-based user groups in the field of nuclear research. The Nuclear Theory effort is closely related to the experimental work in that it provides guidance to experiments along those lines most likely to yield a deeper and more unified understanding of nuclear phenomena, and it helps to interpret experimental results in terms of fundamental theory. Support of work under Nuclear Theory is almost equally divided between national laboratory-based theorists and university-based theorists.

Peer review is used extensively for proposals for: (1) direct funding of university-based scientists who wish to conduct experiments at the national facilities and (2) access to the accelerator installations.

Written proposals for direct funding should be sent to the Department of Energy. In almost all cases, Department staff request active peer scientists to provide written comments on the scientific merit of the proposed research, competence of the proposers to conduct the proposed research, and technical feasibility of the proposed research. These comments are treated as confidential and, upon request, are provided to the proposers without the reviewer's name or address. Decisions on whether or not to fund a specific proposal are based upon these peer review comments, internal Departmental staff review, examination of overall program priorities, and budgetary constraints.

Written proposals for access to the accelerator installations should be sent to the director of the facility

57-279 O - 87 - 48

at which experiments are to be conducted. The respective facility directors can be contacted directly for information on proposal format and timing. Although evaluation procedures vary somewhat from facility to facility, the general practice is to review the proposal by a panel of peer scientists called a Program Advisory Committee (PAC). Typically, PAC meetings are held twice a year at each facility. The scientists proposing experiments are asked to present their proposal orally before the PAC and to answer questions from the PAC. The PAC provides written recommendations to the facility director who then informs the proposer of the results of the proposal review. For further information regarding the location contact, and necessary arrangements for the DOE user facilities, please refer to Reference 2, below.

Office of Program Analysis

Program Objectives
The Office of Program Analysis (OPA) assists the Director, Office of Energy Research, by monitoring the Department's energy research and development programs in order to advise the Secretary regarding any undesirable duplications or gaps in such programs. Its major functions include: assessing the adequacy of the technology base supporting the research and development programs; performing independent analyses and technology assessments; and advising of alternative actions to support policy decisions.

OPA recently concluded an assessment of the accomplishments of the Office of Health and Environmental Research. An ongoing assessment of research needs in Fossil Energy is being conducted by the Coal Combustion Research Working Group. New assessments are being performed by outside contractors in solar thermal conversion, photovoltaics, geothermal, energy conversion and conservation, and nuclear waste management.

Potential Areas for New Research Initiatives
- Foreign Energy Technology Research Status and Directions
- Energy Technology Research Needs Dictated by Environmental or Health Constraints
- Research Needs Associated with the Disposal of Hazardous Wastes (Non-radioactive) from Energy Systems

Proposal Review Procedures
Solicited or unsolicited proposals are subjected to a technical peer review process. Acceptable proposals must provide for technical assessments of long-range, high-risk and high potential payoff research in energy technologies. Proposals for hardware development, development of models or algorithm tools, or experimental efforts, are not acceptable by the office. Proposals will be judged on the basis of their novelty, appropriateness to the Department of Energy's priorities, potential for useful data generation, expected quality of efforts, cost and availability of funds.

Small Business Innovation Research

Program Objectives
The Small Business Innovation Research (SBIR) Program is a new effort at the Department of Energy which was mandated by the Development Act of 1982 (P.L. 97-219) and is administered through the Office of Energy Research. The principal purposes of the SBIR Program are: (1) to stimulate technological innovation; (2) to use small business to meet Federal research and development needs; (3) to foster and encourage participation by minority and disadvantaged persons in technological innovation; and (4) to increase private sector commercialization innovations derived from Federal research and development.

There are three phases to the SBIR program:

Phase I—Proposals are submitted in response to a SBIR program solicitation and are reviewed primarily on the basis of scientific/technical merit, feasibility of ideas, qualifications of the principal investigator, anticipated benefits, and the adequacy of the proposed effort to show progress toward providing feasibility of the concept. Emphasis will be placed on ideas that significantly contribute to energy-related scientific/engineering research or research and development. Approximately 100 awards were made in FY 1983 for Phase I of the SBIR program in amounts ranging up to $50,000 for a period of up to six months.

Phase II—The intent of Phase II is to further develop ideas explored under Phase I. Awards will be made to firms with approaches to problems that appear sufficiently promising under Phase I. It is anticipated that one-third to one-half of Phase I awardees will receive Phase II awards after an evaluation of Phase II proposals. Phase II awards are expected to range from $200,000 to $500,000, for a period of performance not to exceed 24 months.

Phase III—The intent of Phase III is for non-Federal capital interests to convert DOE sponsored efforts (under Phase I and Phase II) into technological innovation. Thus, DOE pays for the prerequisite feasibility and research efforts necessary for follow-on commercialization funding by non-Federal capital interests. Non-SBIR funded production contracts with a Federal agency for products or processes intended for use by the Government are another possibility under Phase III.

Phase I and Phase II awards will both continue in FY 1984 and FY 1985.

Potential Areas for New Research Initiatives

The Department of Energy issues SBIR Program Solicitations annually. There are 25 research areas included in the FY 1984 program solicitation which can be considered representative of topics to be seen in the future program solicitations. These are:

- Materials Science
- Chemical Separations
- Supercomputer Research
- Artificial Intelligence in Advanced Control Systems
- Biological Analyses
- Health and Environmental Effects Instrumentation
- Plasma Diagnostics
- Plasma Confinement Systems Technology
- Fusion Energy Systems
- High Energy Physics Technology and Research
- Particle Accelerator Technology
- Nuclear Physics Instrumentation and Technology
- Fossil Energy Power Generation
- Coal Utilization and Conversion
- Enhanced Oil Recovery and Tar Sands
- Fossil Energy Instrumentation
- Low-level Radioactive Waste Management
- High-level Radioactive Waste Handling and Treatment
- Nuclear Reactor Instrumentation and Technology
- Uranium Enrichment Technology
- Geothermal Technology
- Energy from Municipal Solid Waste
- Biomass Energy Research
- Electrochemistry and Batteries
- Photovoltaic Research

The FY 1984 solicitation was issued in January, 1984. Requests for the solicitation and questions pertaining to the solicitation should be addressed in writing to:

SBIR Program Office
U.S. Department of Energy
Washington, D.C. 20545

For reasons of competitive fairness, oral communications regarding the solicitation are restricted during the proposal preparation period. General questions about the DOE SBIR Program, but not pertaining to the solicitation or to requests for additional copies, can be submitted to the program information contact listed below.

Daniel E. Williams
General University Activities Contact
Telephone Number (515) 294-2635

Ames Laboratory is operated for DOE by Iowa State University under the administrative management of the Chicago Operations Office. The Laboratory conducts research principally in materials sciences centering on the preparation, purification, chemical characterization and structure identification of new materials, followed by evaluation and interpretation of their chemical, physical and mechanical properties. Smaller but unique and vigorous capabilities are maintained in nuclear physics, applied mathematics, coal preparation science, and non-destructive materials testing.

The Laboratory enjoys extensive cooperation with Iowa State University through year-round faculty appointment, graduate student training, and facilities sharing programs. A summer research participation program for undergraduate students and faculty members (primarily from non-local institutions) is also supported by the Laboratory.

Bates Linear Accelerator Facility
Massachusetts Institute of Technology
Post Office Box 95
Middletown, Massachusetts 01949

Irnest Moniz
Director
Telephone Number (617) 245-6600

The Bates Linear Accelerator Facility is operated for the Office of Energy Research by the Massachusetts Institute of Technology (MIT). The Bates installation includes a linear accelerator and recirculation system which provides electron beams with energy up to 750 MeV. The facility also includes magnetic spectrometer systems, detector systems, and computers essential to execution of basic nuclear research experiments. Experimental work at Bates is closely coordinated with a major theory program at MIT. The principal emphasis of the Bates program includes the following: (1) determination of electric charge, magnetic moment, and current distributions in nuclei by high resolution, high precision electron scattering experiments; (2) measurement of electromagnetic properties of nuclear states and nuclear deformation parameters by high-resolution, high precision electron scattering; (3) the investigation of the momentum distribution of nucleons bound within complex nuclei, (4) role of nucleon resonances in nuclear structure, and (5) fundamental pion production amplitudes by means of photon-induced reactions. The capability of the Bates Accelerator for basic studies of electromagnetic properties of nuclei is unique in the United States. Each year approximately forty universities and other institutions participate in basic nuclear research at the Bates facility.

Fermi National Accelerator Laboratory
P.O. Box 500
Batavia, Illinois 60510

Leon Lederman
Director
Telephone Number (312) 840-3211

Philip V. Livdahl
General University Activities Contact
Telephone Number (312) 840-3211

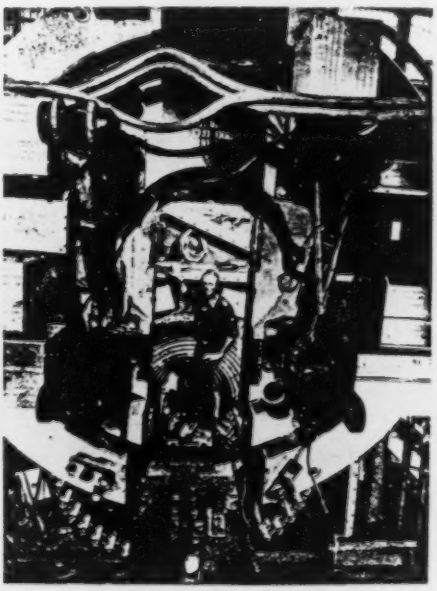
The Fermi National Accelerator Laboratory is operated for the Office of Energy Research by the Universities Research Association, Inc. (URA), a consortium of 54 universities throughout the United States and Canada. Its central purpose is to explore the field of elementary particle physics so that the understanding of the basic structure of matter may be broadened. Related to this purpose is the improvement of accelerator design, which has resulted in numerous technological spin-offs such as the development of various applications for superconductivity, in addition to using it for magnets, fast electronics and particle detector technology, and special computers/computer programs. Additionally, Fermilab's linear accelerator is used in cancer therapy; thus the laboratory has become deeply involved in a project outside high energy physics: a medical radiation therapy facility. The principal scientific instrument is a particle accelerator system, consisting of a series of five accelerators, capable of terminal energies up to 700 billion electron volts (GeV) at the present time. The Laboratory has several major construction projects underway (Energy Saver, Tevatron I and II) which will upgrade the accelerator's capability to 1,000 GeV for fixed target physics and construct a matter-antimatter colliding beams facility at an energy level of 2,000 GeV. This will significantly increase the Laboratory's capability to perform advanced particle physics research.

Notre Dame Radiation Laboratory
University of Notre Dame
Notre Dame, Indiana 46556

Robert H. Schuler
Director
Telephone Number (219) 239-7502

Dr. F. M. Kobayashi
General University Activities Contact
Telephone Number (219) 239-7378

The Notre Dame Radiation Laboratory is operated by Notre Dame University for the Office of Energy Research. Its objective is to study radiation effects—to obtain, through theoretical and experimental research, detailed descriptions of the mechanisms leading to chemical change following the absorption of high-energy radiation and light; and to construct predictive models that will be useful in experimental and technological applications where reactions are initiated by radiation chemical and photochemical methods. The laboratory maintains an outstanding complement of equipment such as linear and Van de Graaff accelerators, cobalt-60 gamma-ray sources, lasers and photochemical sources. Unique facilities include a coupled Van de Graaf-ESR spectrometer for studying radiation produced by visible and ultraviolet light, and computer-controlled apparatus for ready acquisition and processing of optical absorption data in pulse radiolysis and flash photolysis experiments. These facilities are made available to university and individual scientists for appropriate research.



Princeton Plasma Physics Laboratory
Princeton University
P.O. Box 451
Princeton, New Jersey 08544

Harold P. Furth
Director
Telephone Number (609) 683-3555

Robert G. Mills
General University Activities Contact
Telephone Number (609) 683-2469

The Princeton Plasma Physics Laboratory (PPPL), operated by Princeton University for the Office of Energy Research, is one of the major controlled thermonuclear research facilities supported by DOE. Its mission is to produce and control thermonuclear fusion for the purpose of developing an electrical energy source that would be economic, inexhaustible, and environmentally attractive. PPPL is able to conduct experimental, theoretical, and computer investigations into all branches of plasma physics. Currently, the low-density toroidal research at PPPL is leading the world effort in advanced heating methods, attainment of high electron and ion temperatures, and development of detailed diagnostics for high-temperature toroidal plasmas.

Stanford Linear Accelerator Center
P.O. Box 4349
Stanford, California 94305

Dr. W. K. H. Panofsky
Director
Telephone Number (415) 854-3300, X2601

Eugene B. Rickansrud
General University Activities Contact
Telephone Number (415) 854-3300, X2217

The Stanford Linear Accelerator Center is operated by Stanford University for the Office of Energy Research to carry out experimental and theoretical research in high-energy physics, to develop new techniques for particle acceleration and for experimental instrumentation. SLAC's main research instrument is a two mile-long linear electron accelerator, the largest of its kind in the world. This machine is augmented by two electron positron colliding beam storage rings: the 4.5 GeV per beam (9 GeV center of mass) SPEAR ring with two interaction regions; and the 18 GeV per beam (36 GeV center of mass) PEP storage ring with 6 interaction regions. These accelerators are complemented by an impressive array of large detectors including: a hybrid bubble chamber facility; a detector constructed of sodium iodide prisms; and a number of sophisticated magnetic spectrometers, each uniquely optimized for some specific aspect of particle physics detection. The array of detectors is supported by a central computer facility consisting of two IBM 370/168 and one IBM 3081 mainframe central processing units plus associated peripherals. Additionally, SPEAR supports the Stanford Synchrotron Radiation Laboratory which is an independent entity to exploit the synchrotron light emitted as a byproduct of the spear storage ring.

Assistant Secretary for Fossil Energy

General Description

The primary mission of the Fossil Energy (FE) program is to support longer-term, high-risk R&D with high potential payoff that will help increase domestic production of oil and gas or that will permit the nation to shift from the use of oil and gas to more abundant coal and oil shale resources. Near-term technical support for large scale process activities is limited to cases where the government has a unique resource or facility. The longer-range research activities in Fossil Energy focus on acquiring the technology base necessary for industry to develop and demonstrate hardware with minimal government involvement. Specifically, the Fossil Energy role is to support long-term research toward the following objectives:

- Provide an improved capability to convert coal and oil shale to liquid and gaseous fuels;
- Increase domestic production of coal, oil and gas;
- Ensure that current and new facilities that burn coal can do so in an economically viable and environmentally acceptable manner;
- Allow more efficient and more economically attractive utilization of fossil energy resources.

The Fossil Energy activity includes thirteen major programs, grouped under seven program offices and staff groups, which are discussed in the following pages. In addition, the Strategic Petroleum Reserve (SPR) and the Naval Petroleum and Oil Shale Reserves have been assigned to the office. One of these seven program offices is the Office of Technical Coordination, which is the central point of contact for inquiries from universities concerning the Fossil Energy Program.

Program execution is primarily carried out by two energy technology centers. These centers are described in Part III of this guide. Other associated program dedicated research institutions are discussed at the end of this section.

Proposal Review Procedures

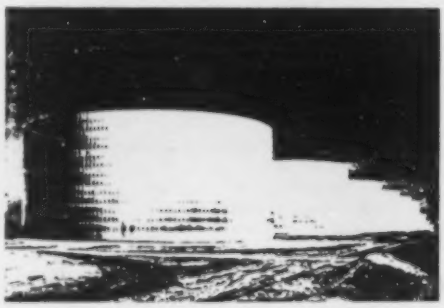
The general policy in Fossil Energy is to assure that there is a central uniform system that identifies, reviews and evaluates unsolicited proposals, preproposals, and revised or renewal proposals. These proposals may be submitted at any time or specifically in response to a solicitation. *The Pittsburgh Energy Technology Center (PETC) is responsible for all such proposals that pertain to any part of the Fossil Energy Program.*

All incoming unsolicited proposals received by FE, including letters of transmittal, will be transmitted to the:

Pittsburgh Energy Technology Center
Attn: Supervisor, Proposal Operations, OP-20
P. O. Box 10940
Pittsburgh, Pennsylvania 15236.

PETC will screen each proposal to determine if it pertains to the Fossil Energy Program. If the proposal does not pertain to the FE Program, PETC will either notify the sender by letter as to where and to whom the proposal should be sent, or they will forward the unsolicited proposal to DOE Headquarters for possible reassignment.

If the proposal does pertain to the FE Program, the proposal will be assigned a number, entered into a tracking log and sent to the most appropriate FE program office. This office will review the proposal and identify at least



two peer reviewers who do not directly work for DOE. PETC will arrange for an outside review and will forward the results to the FE program office for action. Notification of proposal acceptance or rejection is prepared by the proposal operations manager at PETC. If a preproposal has been submitted and the FE program office is interested in reviewing a full proposal, the sender will be so notified.

Somewhat more elaborate procedures are followed when proposals are submitted in response to a Program Solicitation (PS) for the University Coal Research program. Each proposal receives at least four independent peer reviews and are ranked in order of priority by the reviewers at an annual meeting held after individual reviews are complete. Ranking is primarily determined by the quality of the proposal. Top rated proposals receive research grants.

Office of Technical Coordination
Richard J. Bergemann (301) 353-2786

Advanced Process Technology

Program Objective
The Advanced Process Technology (APT) Program is an integral part of DOE's oil, gas, shale, tar sand, and coal liquids research programs. These research programs provide significant underpinning to DOE's emphasis on liquid fuels to satisfy national security and economic welfare strategic needs. The APT Program provides crosscutting advanced exploratory research support in extraction, processing, and utilization technologies that influence all fossil-derived liquid fuels. In addition, the APT Program includes Arctic/Offshore fundamental research projects that will aid the development of these promising oil and gas resource areas.

Potential Areas for New Research Initiatives

Advanced Exploratory Research
- Advanced Extraction Technology
  - — Laboratory studies (and small scale field tests) of the use of microbes to enhance oil recovery;
  - — Advanced extraction instrumentation development;
  - — Environmental impact mitigation research on subsidence and aquifer restoration.
- Fundamental Petroleum Chemistry
  - — Basic research into the physical, chemical, and thermodynamic properties of fossil-derived liquid fuels;
  - — Laboratory research into storage/handling stability problems in heavy crude and shale oil caused by heteroatom content; and
  - — Metals coordination chemistry research.
- Advanced Utilization Technology
  - — Analysis of fuel-sulfur and fuel-nitrogen effects on engine air emissions;
  - — Investigation of fuel hydrogen-to-carbon ratio on engine air emissions; and
  - — Basic engine combustion studies on emerging fossil-derived fuels.

Arctic/Offshore Research
- Ice Characterization
  - — Laboratory and field analysis of ice geometry and forces;
  - — Investigation of the migration and drift of ice islands; and
  - — Development of predictive ice analysis models.
- Seafloor/Soils Research
  - — Permafrost evaluations and mapping for Arctic regions;
  - — Investigation of ice-induced seafloor scouring and gouging phenomena; and
  - — Field application of the Seafloor Earthquake Measurement System (SEMS) to study seafloor stability in the arctic.

Program Information Contact
Advanced Process Technology
Gerald J. Parker (301) 353-3032

Advanced Research and Technology Development

Program Objective
The objectives of the Advanced Research and Technology Development program are to assess and identify long-range advanced research needs in coal processing, fossil fuels utilization and extraction, materials, components, and instrumentation; to provide oversight and technical assessments of ongoing advanced research in fossil energy so as to ensure balance and proper priorities; to initiate and fund projects involving new, exploratory concepts or goal-oriented basic research; to provide for university coal research; and to provide policies for, and overview of, Fossil Energy supported university activities. The Advanced Research and Technology Development program also is designed to provide an effective communications channel between the Fossil Energy program and academic institutions, and to encourage these institutions to become involved in programs related to the DOE Fossil Energy mission.

Areas Covered by Current Projects

Research

- Materials research;
- Coal science;
- Fluids and solids handling;
- Instrumentation and control;
- Component exploratory development;
- Technology transfer;
- Coal characterization and specificity related to liquefaction and gasification processes;
- The structure and reactions of coal and analysis of its conversion products;
- Multiphase flow and thermodynamic phenomena related to coal conversion processes;
- Fundamental problems in combustion of pulverized coal, synfuels and coal-liquid mixtures; and
- Environmental aspects directly related to coal conversion processes and coal utilization.

Program Information Contact
Advanced Research and Technology Development
Richard J. Bergemann (301) 353-2786

Coal Liquefaction

Program Objective
The objectives of the Coal Liquefaction program are to develop advanced technology for the production of liquid fuel from coal to support commercial activity in the private sector based on the following:

- Improved process technology to convert domestic coal into refinery feedstocks, distillate heating oil, gasoline, and chemical feedstocks; and
- Novel and innovative processes in laboratory bench scale units.

Areas Covered by Current Projects

Technology Development

- Coal liquefaction processes, e.g., solvent extraction, catalytic liquefaction, donor two-stage processes and indirect liquefaction;
- Improved components and instrumentation.

Research

- Liquefaction
  - — Extraction
    - — Hydroextraction/desulfurization process research;
  - — Catalytic hydroliquefaction
    - — Exploratory evaluation of catalysts;
    - — Investigation of improved reactor concepts
  - — Indirect Liquefaction (liquids from synthesis gas)
    - — Improve catalysts ;
    - — Improve reactor concepts
  - — Refining and Chemicals
    - — Exploratory refining processes;
    - — Refining of coal-derived synthetic crude oils; and
  - — Supporting Research
    - — Basic chemical and engineering studies, e.g., structure of coal, pre-asphaltenes, mechanism of coal hydroliquefaction, coal/solvent/hydrogen mixing studies, catalytic reactor modeling design studies, preheater studies, role of mineral matter in coal liquefaction.
    - — Environmental and health effects and their mitigation.

Program Information Contact
Coal Liquefaction
James Batchelor (301) 353-3482

Combustion Systems

Program Objective
The activities of this program emphasize furthering the development of technologies that would allow greater coal use; these are coal-based mixtures, atmospheric fluidized bed combustion, pressurized fluidized bed combustion, and novel combustion processes.

Areas Covered by Current Projects

Technology Development

- Atmospheric and fluidized bed combustions systems;
- Advanced Combustors.

Research

- Fluidized bed combustion;
- Coal combustion;
- Coal/water slurry development and combustion;
- Fluid dynamics in coal combustion systems.

Program Information Contact
Combustion Systems
Howard Feibus (301) 353-4348

Control Technology and Coal Preparation

Program Objective
The activities of this program emphasize furthering the development of technologies that will allow for greater utilization of coal in an environmentally acceptable manner. These include: coal characterization and cleaning for both direct utilization and for feedstock in coal conversion processes; combined flue gas cleanup process for single step control of boiler NO_x, SO_x, and particulate emissions; processes for cleanup of hot coal combustion and gasification streams in support of advanced coal utilization systems such as gas turbines and molten carbonate fuel cells, and management of wastes generated in coal conversion and utilization processes.

Areas Covered by Current Projects

Technology Development

- Chemical and physical coal deashing and desulfurization processes and techniques;
- Spray dryer based flue gas cleanup processes;
- Electron radiation catalyzed, simultaneous SO_2/NO_2 cleanup processes;
- Particulate and alkali cleanup of hot combustion and gasification streams;
- Instrumentation for real time, in situ measurement of contaminants partial PPM levels at elevated temperature and pressure;
- Coal preparation processes and techniques for more efficient removal of sulfur and ash, retention of coal fines and dewatering.

Research

- Pollutant formation and reaction chemistry;
- High temperature gas stream desulfurization;
- Ammonia decomposition catalysis at high temperature;
- Control techniques for organic compounds and trace metals at high temperature;
- Combustion modification for NO_x and particulate control;
- Waste disposal (Fixation/stabilization, soil attenuation, size monitoring);
- Technical and economic assessments;
- Evaluation and characterization of coal and coal waste properties;
- Innovative coal preparation concepts.

Program Information Contact
Control Technology and Coal Preparation
Howard Feibus (301) 353-4348

Enhanced Oil Recovery

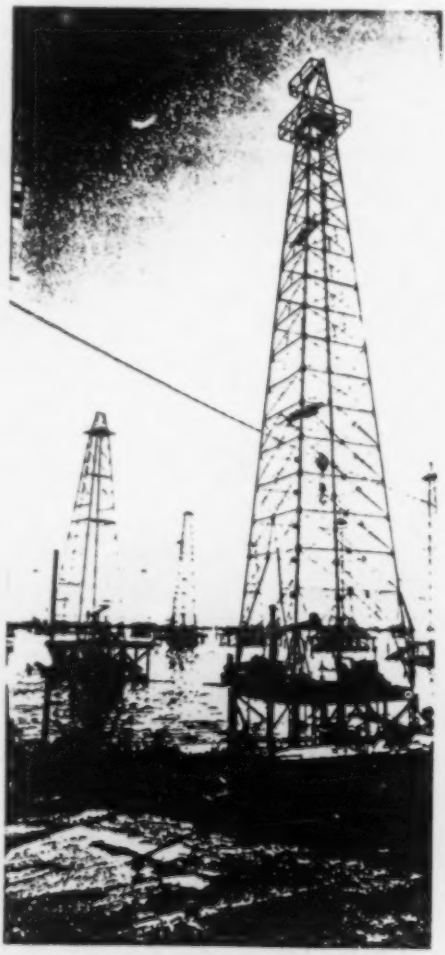
Program Objective

The objective of the Enhanced Oil Recovery (EOR) program is to conduct technology base R&D activities of the generic kind, to assist industry to obtain a better understanding of the mechanisms and behavior of advanced and novel EOR processes for light oil, heavy oil, and tar sand resources.

Because private industry can be expected to continue to improve upon existing EOR processes and to eventually develop new research areas in response to oil price increases, the EOR program now directs its primary emphasis on long- range, high-risk, technology base research with the main thrust on those elements that attract limited or no private venture capital, either because the risks are too high or the payoffs are too far in the future.

Potential Areas for New Research Initiatives

- Fundamental physical and chemical surface phenomena, when enhanced oil recovery (EOR) fluids are injected into petroleum reservoirs;
- Disposal of oil field brines containing EOR chemicals;
- Efficiency of crude oil recovery using gas such as N_2 or CO_2;



- Research on a process allowing mobility control to reduce gravity override and fingering in the recovery of heavy oil;
- Inorganic surfactants;
- Advanced/novel processes for EOR and tar sand extraction;
- Assess the effects of reservoir parameters such as temperature and wettability or relative permeability to oil and water.

Fuel Cells (Including Thermionics)

Program Objective

Fuel cells are electrochemical devices which convert the chemical energy contained in the gases generated in hydrocarbon fuel combustion directly into electricity. The objective of the program is to develop fuel cell technology for electric utility and on-site electric power generation systems and for industrial cogeneration applications. Work on advanced fuel cell concepts includes the development of fuel cells for military and transportation applications, and for the direct conversion of coal.

Included in the fuel cell program, although not a fuel cell, is thermionic energy conversion. It is electrothermal. Carnot cycle technology wherein thermal energy of hydrocarbon fuel combustion (or solar, nuclear fission or fusion, or MHD exhaust heat) is converted directly into electricity. The objective of this program is to develop thermionics for topping gas turbine combustion chambers for combined cycle electric utility power generation and for industrial cogeneration applications.

A summary of the major areas being investigated follows:

- Phosphoric acid fuel cell systems:
  - — 4.8 megawatt electric utility powerplant;
  - — 40 kilowatt on-site, integrated power system.
- Molten carbonate fuel cell system:
  - — Coal gas fueled electric utility system;
  - — Industrial cogeneration systems.
- Solid oxide and advanced fuel concepts:
  - — Solid oxide electrolyte, high temperature fuel cell technology for electric utility, on-site and industrial cogeneration;
  - — Advanced fuel cell technology for military and transportation applications;
  - — Thermionic topping of combustion chamber of gas turbine combined cycle gasification powerplant.
- Industrial cogeneration applications using a thermionic burner;
- Technology base development.

Potential Areas for News Research Initiatives

- Surface catalysis;
- Fuel cell oxygen electrodes;
- Electrode and matrix materials development;
- Contamination tolerance;
- Theoretical and experimental plasma physics;
- High temperature, protective ceramic coatings development.

Research

- Relevant combustion phenomena
- Supporting fuel studies

Fuel Cells
George Rudins (301) 353-5910

Heat Engines

Program Objective

Research and development under this program is aimed towards coal-fueled gas turbine and diesel engine technologies. Users of these power systems face long-range uncertainties in the cost and availability of clean distillate and natural gas fuels upon which they normally depend. The program's principal purpose is to establish a firm technology base in combustion, thermal design, and supporting disciplines that would facilitate full scale commercial development by the private sector in the mid 1990's.

Areas Covered by Current Projects

Technology Development

- Combustor design
- Turbine cooling technology
- Bench scale development testing
- Fuels evaluation

Program Information Contact
Heat Engines
George Rudins (301) 353-5910

Magnetohydrodynamics

Program Objective

The objective of the Magnetohydrodynamics (MHD) program is to establish a suitable MHD technology base to allow industrial commercialization of MHD power plants in the future. MHD is a Carnot cycle system involving the direct conversion of thermal energy generated by the combustion of coal into electric power.

Areas Covered by Current Projects

- Technology Development
  - — Open-cycle MHD system components and subsystems testing.
- Research
  - — Basic and engineering studies on the subsystems of MHD close cycle processes.

Program Information Contact
Magnetohydrodynamics
George Rudins (301) 353-5910

Oil Shale

Program Objective

The primary objective of the Oil Shale program is to develop a sound base of technical information that will assist and support industry so that more of the Nation's oil shale resources can be utilized in an economical and environmentally acceptable manner. There are two interrelated objectives:

- The development of a sound engineering and scientific information base having broad application to the design of recovery processes that will be characterized by reduced cost and enhanced environmental acceptability; and the development, through proof-of-concept of novel ideas evolving from this work.
- The characterization of waste streams from oil shale conversion processes; and the design, test and evaluation of environmental control technologies applicable to oil shale processes.

Potential Areas for New Research Initiatives

- New approaches to control of emissions from oil shale retorting operations.
- New concepts to recover oil and energy values from oil shales.
- Develop new instrumentation techniques as applied to oil shale technology.
- Generic research to improve understanding of dynamic systems in shale processing.

Oil Shale
Jerry W. Ramsey (301) 353-3514

Surface Coal Gasification

Program Objective

The Surface Coal Gasification program has the mission of, and responsibility for, initiating and developing new technologies leading to commercially viable gasification process, components, and systems for converting coal to high, medium or low Btu gaseous and/or synthesis gas suitable for subsequent conversion into chemical feedstocks or liquid fuels. The program is responsible for the planning, coordination and effectiveness of process development programs as are performed in integrated benchscale systems, process development units (PDU) and, in some cases, pilot plants. Exploratory research and advanced development projects and/or studies are an important part of this activity. The program provides technical support and coordination with universities, industry, the Synthetic Fuels Corporation (SFC), the Tennessee Valley Authority (TVA), and other governmental agencies, as required, in order to accomplish the objectives of the Surface Coal Gasification program.

Areas Covered by Current Projects

Technology Development

- Coal Gasification Processes—e.g., high, medium, low Btu gases, synthesis gas, hydrogasification, catalytic gasification.
- Gas Treatment/Cleanup Systems—e.g., acid gas removal, sulfur removal, tar/phenol decomposition and/or removal, etc.
- Waste Water/Effluent Treatment, and Control—e.g., impact of zero effluent discharge requirements, cooling tower studies, biologic treatment systems, process water reuse, etc.
- Operating Components, Materials Applications, Instruments, and Control Techniques—e.g., high performance valves, pumps, compressors, new alloys, coatings, claddings, new measurement techniques, instruments, etc.
- Modeling and systems analysis—e.g., process analysis, comparative economic systems, reactor modeling, data base management.

Research

- Fundamental Studies
  - — Modeling
  - — Kinetics
  - — Thermodynamics
  - — Catalysis & Reactions
  - — Mechanisms
  - — Hydrogasification
  - — Pyrolysis
  - — Fluidization
  - — Acid Gas Removal
  - — Hot Gas Removal
  - — Gas Separation
  - — Conversions
- Novel Gasification Concepts
  - — High Btu Processes
  - — Medium Btu Processes
  - — Low Btu Processes
- Environmental
  - — Waste Water Treatment
  - — Environmental Technology

Unconventional Gas Recovery/ Underground Coal Gasification

Program Objective

The main objective of the Unconventional Gas program is to augment domestic gas supply through unconventional geologic sources. The current objectives of this program include: demonstration of field performance and acceptable predictive modeling capability for production of gas from unconventional gas sources; development of cost-effective diagnostic and extraction technologies required to produce gas efficiently and economically, and establishment of the necessary technology base in order to be able to identify production potentials from low permeability gas formations.

Areas Covered by Current Projects

Technology Development

- Gas recovery from Devonian shales;
- Gas recovery from western gas sands;
- Gas recovery from hydrates, deep sources, and coal seams.

Research

- Engineering and basic studies on gas recovery from Devonian shales, western gas sands, hydrates, deep gas sources, and coal seams.

Program Dedicated Facilities

Grand Forks Project Office (GFPO)
P.O. Box 7206, University Station
Grand Forks, North Dakota 58202

Harvey M. Ness
Director
Telephone Number: (701) 795-8170

The project office plans and manages the Department of Energy's contract research in low-rank coal and provides technical and financial oversight of this research and of the cooperative agreement with the University of North Dakota's Energy Research Center. In addition, the project office assists in the monitoring of the Great Plains Gasification Project at Beulah, North Dakota. The project office is under the direct management control of the Morgantown Energy Technology Center.

University of North Dakota Energy Research Center (UNDERC)
P.O. Box 8213, University Station
Grand Forks, North Dakota 58202

George A. Wiltsee
Director
Telephone Number: (701) 777-5134

Formerly known as the Grand Forks Energy Technology Center, the University of North Dakota Energy Research Center (UNDERC) is the center for research and applications of low-rank coals, which include lignite, subbituminous coal and peat. It conducts research for low-rank coals in environmental control technology, solvent liquefaction, atmospheric fluidized bed combustion, pulverized coal combustion, coal preparation, and slagging fixed-bed gasification to identify the technical, political, environmental, and economic restraints to expanded production of low-rank coals.

Laramie Project Office (LPO)
P.O. Box 1189
Laramie, Wyoming 82070

William E. Little
Director
Telephone Number: (307) 721-2247

The project office plans and manages the Department of Energy's contract research in oil shale, tar sands and underground coal conversion and provides technical and financial oversight of this research and of the cooperative agreement with the University of Wyoming's Western Research Institute. The project office is under the direct management control of the Morgantown Energy Technology Center.

Western Research Institute (WRI)
P.O. Box 3395, University Station
Laramie, Wyoming 82071

Wesley E. Barnes
Managing Director
Telephone Number: (307) 721-2212

Formerly known as the Laramie Energy Technology Center, the University of Wyoming's Western Research Institute is the center for research and applications related to oil shale, tar sands and underground coal gasification. Oil shale activities center around the development of processing technologies and environmental controls for the economical and safe production of shale oil. Tar sands research seeks to determine the recovery potential of domestic tar sands and the technology requirements for the recovery of oil. In underground coal gasification, the goal is to develop the technology to produce from coal deposits clean fuels suitable for commercial exploitation by conventional techniques.

Bartlesville Project Office (BPO)
U.S. Department of Energy
P.O. Box 1398
Bartlesville, Oklahoma 74005

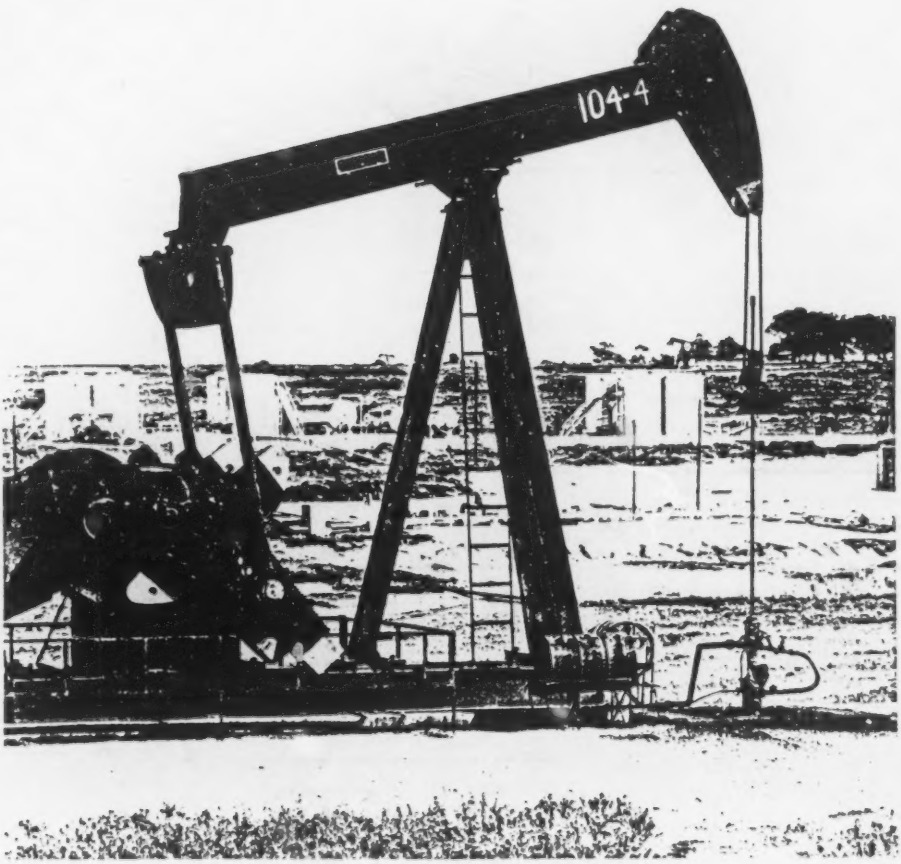
Robert L. Folstein
Director
Telephone Number: (918) 336-2400 x401

The project office plans and manages the Department of Energy's contract research in petroleum including enhanced oil recovery, fundamental hydrocarbon petroleum chemistry, thermodynamics, liquid hydrocarbon upgrading and processing, liquid fuels utilization and environmental and unconventional natural gas R&D. In addition, it provides technical and financial oversight of this research and the cooperative agreement with the National Institute for Petroleum and Energy Research, a government-owned laboratory run by IIT Research Institute. The project office is under the direct management control of the Assistant Secretary for Fossil Energy.

National Institute for Petroleum and Energy Research (NIPER)
P.O. Box 2128
Bartlesville, Oklahoma 74005

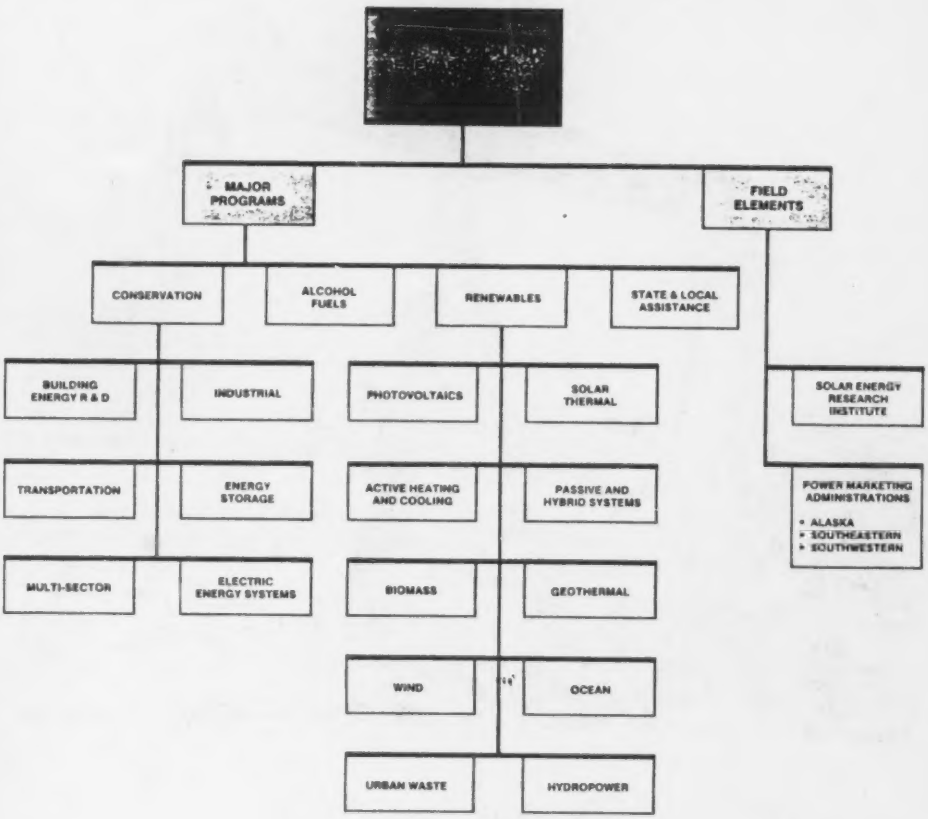
Richard Snow
Director
Telephone Number: (918) 336-2400 x200

Formerly known as the Bartlesville Energy Technology Center, the National Institute for Petroleum and Energy Research is a government owned facility that is operated by the Illinois Institute of Technology Research Institute (IIT) as a center for research on petroleum and other fossil fuel liquids. NIPER has active programs in enhanced oil recovery research including chemical flooding, carbon dioxide flooding and thermal treatments among others. Fuel utilization research encompasses the end-use requirements of the liquid fossil fuel cycle, including the characterization of new reference fuels, research on compatible end use systems to optimize energy usage and diesel engine research for stationary applications that is aimed toward operation with coal derived liquid fuels. Basic research on the physical, chemical and thermodynamic properties of fossil fuel liquids is also actively pursued.



104-4

Conservation and Renewable Energy



Assistant Secretary for Conservation and Renewable Energy

General Description

The Assistant Secretary for Conservation Renewable Energy is responsible both for programs which increase the efficiency of energy utilization and the amount of energy produced from renewable sources; and for the oversight and coordination of the Alaskan, Southeastern and Southwestern Power Marketing Administrations. The Conservation programs include: Building Energy R&D, Vehicle Energy R&D, Industrial, Energy Systems Research, Energy Storage, and Electric Energy Systems. Renewable Energy programs encompass: Photovoltaics, Solar Thermal, Geothermal, Biomass, Wind, Ocean, Active Solar, Passive Solar, Urban Waste, Hydropower and Alcohol Fuels. Power Marketing is comprised of five Administrations; i.e., Alaska, Bonneville, Southwestern, Southeastern and Western Area Power. Both Bonneville and Western Area Power Administrations report directly to the Secretary.

To achieve the energy conservation mission, selective problem-oriented basic research is conducted to develop a generic technology base that will support private sector initiatives to improve energy conversion and utilization. This enables the private sector to design and develop processes and equipment applicable to the transportation, buildings and industrial end-use sectors.

Renewables are inexhaustible or endlessly regenerative and can be grouped into two major categories: dispersed technologies applied directly by end-users and technologies for centralized utility applications. The objective of the renewable energy programs is achieved through research, development and proof-of-concept experiments to enable industry to bring efficient, economically competitive and environmentally acceptable renewable energy resources and technology options into the marketplace.

In this way, the Conservation and Renewable programs support research which attracts limited or no private venture capital because the risks are too high or the payoff is too long-range or unpredictable.

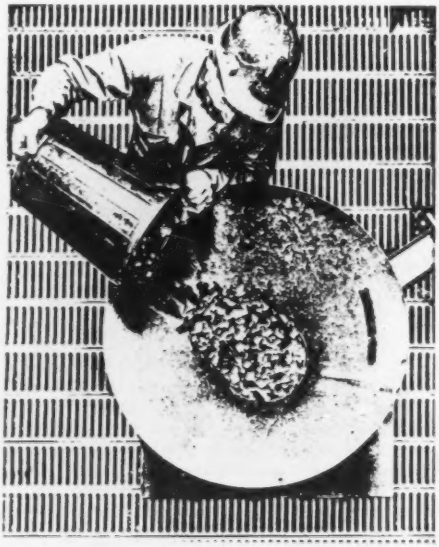
The third major area of responsibility for the Assistant Secretary is the oversight and coordination of policies and activities of three of the five Power Marketing Administrations to insure that Federal hydropower is marketed to promote widespread use at lowest cost and to promote energy conservation and the use of energy from renewable sources.

Field Elements

The Solar Energy Research Institute (SERI), Golden, Colorado, is the Nation's primary Federal laboratory for solar energy research and performs functions assigned by the Department of Energy in research, development and testing. SERI carries out its mission by conducting and coordinating long-term, high-risk research and development on renewable energy technologies which show promising evidence of ultimately competing in the marketplace, and which private industry cannot reasonably be expected to undertake. SERI's principal responsibilities are to carry out advanced scientific research in order to develop new technological options.

Proposal Review Procedures

Exceptions to the proposal review procedures discussed below may be found in the individual program summaries.



Unsolicited Proposals

Unsolicited proposals for submission to the Office of Conservation and Renewable Energy should be sent to:

Unsolicited Proposal Coordinator
Reports and Analysis Branch
Procurement and Assistance Management Directorate
U.S. Department of Energy
Washington, D.C. 20585

When an unsolicited proposal is received, it is first logged into the Procurement proposal tracking system and then referred to the appropriate program area for review. Program staff generally perform a preliminary review of the proposal to determine its relevance to program goals. If a proposal is deemed germane, a technical review will be performed either by program

staff, field personnel or peer groups. During the evaluation of the proposal, negotiations may take place to clarify the specific tasks of the proposed work. Based on the results of the technical review and the availability of funds, staff will then notify the proposer of acceptance or rejection of the proposal.

The Division of Technology Development and Analysis has decentralized project management for advanced heat engines, heavy duty transport and alternative fuels utilization to the National Aeronautics and Space Administration (NASA) Lewis Research Center in Cleveland, Ohio, and for advanced materials development to the Oak Ridge National Laboratory in Oak Ridge, Tennessee. Although DOE personnel may be contacted to discuss overall program research and development requirements, proposals will be directed to NASA and Oak Ridge National Laboratory for review.

CONSERVATION

The goal of the Energy Conservation R&D Program is to conduct scientific and technical research in fields where new knowledge can expand the generic technology base underlying energy conservation. This will allow the private sector to develop ways to make more efficient use of available energy and to facilitate use of nonpetroleum energy sources. Programs in this research area include: Building Energy R&D, Energy Systems Research, Energy Storage, Electric Energy Systems, Industrial and Vehicle Energy R&D.

Building Energy Research and Development

Program Objectives
The Office of Building Energy Research and Development (formerly Buildings and Community Systems) supports activities designed to increase energy utilization efficiency in commercial, residential and Federal buildings, and in entire communities through use of integrated community energy systems. Both research and development programs and regulatory approaches are used to encourage the adoption of energy conservation technologies. Efforts to increase the efficiency of consumer products and to transfer energy-efficient technologies to the private sector are vital aspects of the endeavor. (Although formerly a part of this office, programs to increase the use of urban waste as a source of energy are now administered by the Office of Renewable Technology.)

Potential Areas for New Research Initiatives
- Development of new concepts in building thermal envelope systems to provide better insulation, less infiltration, control of natural and artificial light, improved vapor barrier systems and better weathering.
- Development of test methods and procedures for determining static and dynamic thermal performance characteristics of materials, components and building systems.
- Determination of properties of insulating materials, including dependence of the properties on temperature, density and moisture.
- Increased research in indoor air quality, heat transfer, materials, structures and control technologies.
- Development of novel engine-drive/compressor systems for thermally activated heat pumps.
- Development of heat exchanger and combustion technologies employing new materials and processes to increase efficiency.
- Research on gas isotope enrichment, separation processes and lamp gas mixtures.
- Research on frosting/defrosting, cycling, fluid pairs and advanced insulation materials to improve refrigeration system efficiency.
- Systems analysis and research on thermodynamics, heat transfer, materials, structures, control technologies, combustion processes, and thermochemical/electrochemical processes as applied to community energy systems.

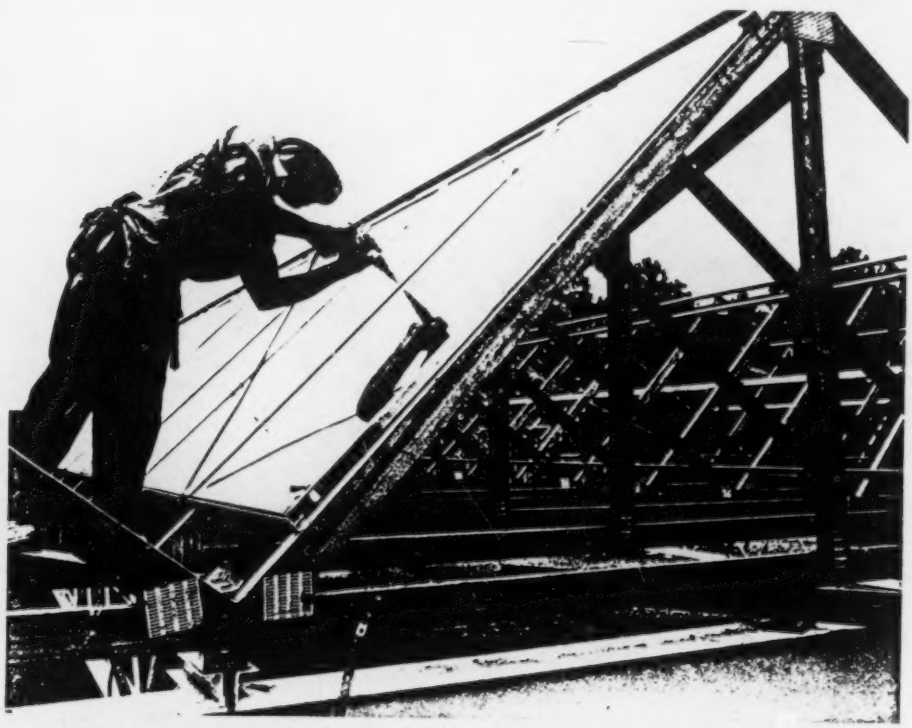
Linda De La Croix (202) 252-9446

Energy Conversion and Utilization Technologies

Program Objectives
The Energy Conversion and Utilization Technologies (ECUT) program focuses on the development of advanced energy conversion and utilization technologies to improve energy efficiency, energy productivity, and fuel-switching capability for transportation, industry, residential/commercial and utility end-use sectors. Research is long-term, high risk applied and exploratory in nature, performed to establish the technical and economic feasibility of advanced energy conversion and utilization systems. Programs are developed and aimed at enhancing technology base and improving analytical capabilities in such research activities as engine combustion technology, tribology, and materials. To perform these tasks, ECUT maintains cooperative efforts with academia, national laboratories, and industry affording considerable opportunity for interdisciplinary review of technology needs, potential solutions to real problems, and effective technology transfer. ECUT programs are designed to provide developers of energy conversion and use technologies with comprehensive data bases and analytical and measurement techniques which will contribute to production of more efficient and reliable systems and components.



Problem Areas Requiring Additional Research

- Energy conversion technology—thermodynamics and fluid mechanics of closed system energy conversion, combustion processes of internal combustion engines, and physical and chemical aspects of alternative fuels for furnaces and boilers.
- Energy utilization technologies—study of heat transfer in harsh environments, physical and chemical separation techniques, and other energy intense processes, physical properties and structures of materials for using high temperature environments, and for reducing losses due to friction and wear.

Potential Areas for New Research

- Energy Conversion Technology
  - — Development of a complete understanding of velocities and turbulence levels at various points during engine operation, and how they can be controlled to appropriately tailor combustion processes of advanced engine concepts.
  - — Complete incorporation of technology base information and development of validated multi-dimensional large-scale computer models of complete engines for use in solving specific design problems.
  - — Assemblage of adequate data base of physical and chemical properties for select alternative fuels and experimentally evaluate several combustion parameters of interest to designers of furnaces and boilers.
  - — Experimental and analytical investigation of thermodynamics and fluid dynamics aspects of advanced closed cycle systems and components.
- Energy Utilization Technology
  - — Development of data bank for flow-induced vibration and two phase-flow studies in shell-and-tube heat exchangers, and investigation of coating techniques to enhance corrosion resistance of heat exchangers in moderate to high-temperature environments.
  - — Research on engineering of biocatalyzed processes for the production of bulk chemical commodities; definition of solvent/membrane characteristics to improve chemical separation techniques.
  - — Identificaion and testing of materials and lubricants with friction reducing characteristics.

Electric Energy Systems

Program Objectives

The Division of Electric Energy Systems has as its primary concern those technologies relevant and applicable to U.S. electric energy systems. The overall objectives of the Electric Energy Systems program are to assist the private sector in the development of: (1) advanced technology options for the Nation's electric energy networks; (2) methodologies for integrating new technologies into electric utility systems; and (3) analytical procedures to assess and enhance the stability and efficiency of the country's increasingly complex interconnected electric energy system. Public concerns over health and safety, reliability, and costs have led to the initiation of innovative research in such areas as high-voltage systems, new materials, and sophisticated control methods.

The primary concerns of the program are:

- To accelerate the introduction of technology options that are critical for maintaining the country's electricity supply system (in both normal and emergency conditions) in a reliable, economic, and environmentally safe manner;
- To develop improved methodologies for planning and controlling complex, high-power electric systems;
- To support basic research on increasing the efficiency of electric energy supply and distribution, thus reducing primary energy use per unit of real GNP.

Potential Areas of New Research Initiatives

- Reliable Electric Power Delivery—Recent breakthroughs in new materials and control concepts show the potential for significantly improving our ability to maintain electric power continuity during periods of severe emergencies. New research is needed in such areas as: electromagnetic pulse protection, basic mechanisms of insulation failure, emergency detection and control, new systems analysis and equipment research, and system dynamic performance.
- Electric Field Effects—Public concern continues over the biological effects on humans, plants and animals from exposure to electric and magnetic fields arising from high voltage transmission of electric power. Research is needed in the low frequency range to clarify issues, to determine the threshold of effects and to assess the risk of undesirable effects from exposure to high voltage transmission lines.
- Systems Technologies—Increased system efficiency, greater fuel displacement (substitution of coal, nuclear and renewable resources for scarce, costly fuels), and enhanced resource management are attainable through research in advanced optimization concepts, and materials and systems technologies. Opportunities for new research exist in such areas as: superconducting power generation and transmission technologies; underground and submarine cables; advanced electrical insulation technology; high efficiency materials; advanced batteries for utility storage; communication and control concepts; multiterminal, high-voltage, direct current transmission systems; and advanced systems simulation analytical methods.

Energy from Municipal Waste

Program Objective

The DOE Energy from Municipal Waste program seeks to provide the generic technology and data base with which local government and private industry can bring Energy from Municipal Waste technologies into the marketplace and increase the efficiency of energy production and utilization. Research is conducted to provide a data base on liquids and gas production and to provide a basis for environmental and feedstocks preparation.

Potential Areas for New Research Initiatives

- Thermochemical studies to provide a generic technology base for systems producing liquid and gaseous fuels.
  - — Combustion tasks concerned with kinetics, efficiency, and products formation for corrosion and pollution control.
  - — Pyrolysis tasks concerned with base data development on effects of various feedstock components and of time, temperature, pressure, etc.
- Biochemical studies to provide data on biochemistry and life support systems of anaerobes. Water and wastewater studies to provide information to improve energy efficiency in treatment systems.
- Mechanical studies to provide generic data on processing generic data on systems design will be developed for use by design engineers. Improved densification techniques and binders.

Program Information Contact

Donald K. Walter (202) 252-6104

Energy Storage Systems

Program Objectives

Energy Storage supports end-use programs in their critical energy-saving and fuel substitution missions. When used in the link between energy source and end-use, storage can correct the timing mismatch between energy supply and energy demand found in most energy delivery systems. This is particularly important in the case of intermittent energy sources such as solar, or in production and delivery systems where demand fluctuates greatly, as with electricity.

The Energy Storage Program goals are to increase the substitution of coal, nuclear and solar energy for petroleum and natural gas; to enable solar and other intermittent

energy systems to provide continuous service; and to conserve energy by storing industrial and utility reject heat for later use and by improving the efficiency of electrochemical processes.

DOE is developing four major energy storage technologies: (1) battery; (2) mechanical; (3) thermal; and (4) chemical energy storage. These technologies will be used throughout the U.S. economy in solar systems, transportation, building heating and cooling, industry, and the utilities.

Problem Areas Requiring Additional Research

- Development of cost-effective batteries with high energy density and peak power capacity, as well as long cycle life for transportation, solar, and utility applications;
- Electrochemical energy conversion, including regenerative EMF systems, fuel cells, etc;
- Development of new methods of hydrogen production from water, using heat or sunlight;
- Development of higher-temperature superconductors;
- Development of more efficient heat transport process investigation into reversible thermochemical reactions;
- Development of a data base containing the thermophysical properties of materials used in energy storage systems.

Potential Areas for New Research Initiatives

- Theory and properties of aqueous, nonaqueous, and solid electrolytes;
- Membrane properties and characteristics of ion exchange materials;
- Structural aspects of electrolytic interfaces, particularly solid-liquid;
- Electric double-layer phenomena at solid-liquid interfaces;
- Characteristics of mechanisms and rates of electrochemical reactions in electrolytic solutions;
- Electrocatalytic theory and material properties for increasing and controlling electrochemical reaction rates;
- Experimental methods and instrumentation in electrochemical kinetic theory research and development;
- Theory and characteristics of electrocrystallization and material dissolution;
- Electrolytic corrosion and passivation theory and technique for electrolytic materials treatment and stabilization;
- Mechanisms of electrophoretic deposition and materials characteristics;
- Electrochemical ion transport phenomena mechanisms and characteristics;
- Materials research relative to electrochemical systems;
- Thermochemical reactions and reactant properties for heat transport;
- Solid-solid phase change materials for thermal storage.

Energy Storage Systems
John J. Brogan (202) 252-1477

Industrial Programs

Program Objectives

The Industrial Programs identify energy conserving industrial techniques and sponsor cost-shared research and development to develop and transfer technology to the private sector. Program efforts are aimed at increasing energy utilization efficiency, substituting more abundant fuels for scarce oil and natural gas in the industrial and agricultural sectors, and minimizing energy loss in waste streams of all types. To complement these efforts, programs are maintained to monitor industry's progress toward improved energy efficiency and to transfer existing and new technology to the private sector. The overall emphasis of these efforts is to encourage an increase in the rate of adoption of energy conservation measures and investments by the industrial sector and to accelerate the introduction of higher-risk technologies which offer significant energy conservation potential.

Problem Areas Requiring Research

- Waste energy utilization and cogeneration—basic work in thermodynamics, heat transfer, materials, combustion processes, and thermochemical/electrochemical processes;
- Alternative materials utilization—basic research on physical properties and structures of proposed alternative materials, and materials recovery techniques;
- High and low temperature processes—basic work in phase equilibria, metallurgy, solids flow, process control technology, and improved materials; and
- Agriculture and food processes—basic research in nitrogen fixation, food preservation, and advanced food processing.

Potential Areas for New Research Initiatives

- Improvement of combustion efficiency through better control of turbulence and reaction rates;
- Research on the chemical kinetics of important processes, especially heterogeneous gas solid and gas liquid kinetics;
- Development of ceramics, metal alloys, and coatings for high-temperature applications;
- Development of research techniques that explore the chemistry and physics of membrane separation of air into nitrogen-rich and oxygen-rich streams, and for separation of mixed liquid streams;
- Development of models of the thermodynamic properties of important materials;
- Basic research in metal solidification processes, nature of coking phenomenon, basic mechanisms of ore grinding, and iron oxide reduction;

- Development of artificial photosynthesis techniques;
- Development of advanced separation techniques for more efficient water removal from solids and liquids; and
- Research on catalysts and catalytic reactions for low temperature chemical processing.

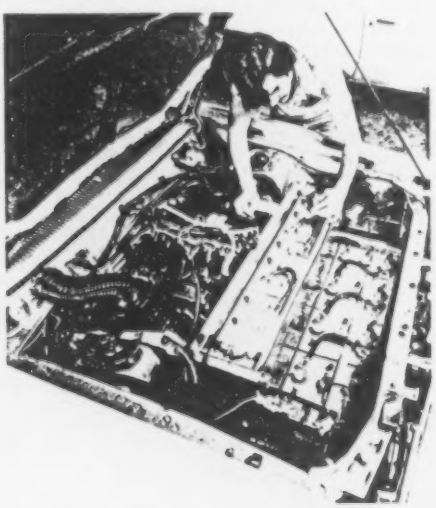
Vehicle and Engine R&D

Program Objectives

The Vehicle and Engine R&D programs are aimed at reducing the transportation sector's vulnerability to petroleum shortages by developing more energy efficient vehicle propulsion system options and by developing the ability to switch from petroleum to electricity and alternative fuels. Emphasis is placed on advancing heat engine technology through the development of component and materials technologies; supporting long-term, high-risk technology research and development for petroleum savings in the heavy duty transport sector; advancing electric and hybrid vehicle technology; and developing means of using alternative fuels in vehicles.



Potential Areas for New Research Initiatives

- Develoment of new concepts and techniques for assessing and utilizing fuels from synthetic crude oil;
- Lightweight hydrogen storage materials or techniques for hydrogen-fueled vehicles;
- Data on composition of exhaust from combustion and synthetic fuels;
- High-strength, high-temperature ceramics; and
- High-temperature waste heat utilization concepts.

In addition, goal-oriented research related to battery development is needed in the following areas:

- Corrosion in battery and fuel cell environments;
- Ionic conductivity of solid electrolytes;
- Catalysts associated with air electrodes and hydrocarbon reformers;
- Material migration;
- Electronic conductivity of sulfur compound electrodes;
- Low-cost electronic insulators;
- Surface phenomena of porous electrodes; and
- Organic electrolytes for secondary batteries.

RENEWABLE ENERGY

Renewable energy resources offer the potential for significant contributions toward achieving energy self-sufficiency over the long-term. In addition to the direct solar energy technologies, such as photovoltaics, active/passive solar and thermal, this category also includes R&D in biomass, ocean, wind and geothermal energy technology.

Active Heating and Cooling

Program Objective

The DOE Active Heating and Cooling program seeks to improve the performance/cost ratio of active solar space conditioning systems by a factor of two-to-four. Research and development are performed on materials, components and prototype systems.

Potential Areas for New Research Initiatives

- Develop and test polymeric collectors to reduce cost and improve performance;
- Test and evaluate performance of evacuated tube collectors and compound parabolic concentrators;
- Research to obtain information on solid desiccant cooling systems.

Biomass Energy Technology

Program Objective
The DOE Biomass Energy Technology program seeks to provide the generic technology base for biomass energy production and conversion which reduces uncertainty to the point at which industry will invest in biomass technology development.

Potential Areas for New Research Initiatives
- Attain understanding of fundamental processes for thermochemical conversion of biomass into gaseous and liquid fuels.
- Establish the technology data base for photobiological production of hydrogen.
- Establish a suitable technology base and basic understanding of the biological conversion of cellulosic material.
- Examine aquatic species production through species screening and improved cultural practices.

Geothermal and Hydroelectric Energy Technologies

Program Objectives
The objective of the Geothermal and Hydropower programs is to build a broad technology base that will be used by the private sector to exploit the Nation's extensive geothermal resources (hydrothermal, geopressured, and hot dry rock) and small-scale hydropower resources. Research efforts related to hydrothermal resources address risks perceived by the private sector in the area of reservoir capacity and longevity, the high cost of exploration and reservoir development, commercial scale plant economics, environmental effects of production, and unproven energy extraction and conversion technologies. Geopressured wells are being tested to determine magnitude, availability and producibility of geopressured resources for recovery of methane, and hydraulic and thermal energy. The technical feasibility of extracting thermal energy from hot dry rock resources is being determined by creating and operating a large scale multifracture thermal loop in deep rock formations. R&D efforts related to small-scale hydropower resources have involved field tests of minimum stream flow requirements and Schneider engine and marine thruster engineering development.

Potential Areas for New Research Initiatives
- Development of drilling equipment and techniques that will lead to higher penetration rates, longer bit lives, and improved directional drilling.
- Development of electronics and instrumentation for mapping wellbore fractures, assessing the integrity of the cement bond, and determining the trajectory of the wellbore.
- Evaluation of precipitation and scale control techniques, brine treatment/disposal, and cooling water systems.
- Development of non-destructive evaluation techniques for drilling components, well completion materials, and energy conversion component materials in order to predict and prevent failure.
- Development of more accurate and cost-efficient tools, techniques and models for geothermal exploration leading to the improvement of geochemical and high-resolution geophysical techniques for all types of hydrothermal reservoirs.
- Development of improved reservoir engineering techniques for determination of the extent of a reservoir and its porosity, permeability, and recharge mechanism through improved well testing, log interpretation and reservoir modeling techniques.
- Injection of spent geothermal brines into deep reservoir formations, including study of the need for and techniques for chemical pre-treatment and solids removal.

Ocean Energy Technology

Program Objective
The DOE Ocean Energy Technology program seeks to provide a technology base that will enable private industry to develop and commercialize ocean energy technology.

Potential Areas for New Research Initiatives
- Development of materials and manufacturing processes for higher efficiency that can be obtained with current state-of-the-art heat exchangers operating at temperature differences of approximately 20°C.

Proposal Review Procedure
After a proposal has been logged into the DOE proposal tracking system, it is either evaluated by the Headquarters program staff or forwarded to the proper DOE laboratory for review and action. The forwarding of the proposal to the DOE laboratory is the normal course of action. Based on the results of the technical review and the availability of funds, staff will then notify the proposer of acceptance or rejection of the proposal.

Passive and Hybrid Solar Program

Program Objectives

The DOE Passive and Hybrid Solar Program seeks to improve performance of passive and hybrid (mixed active and passive) solar buildings through research and development on systems, components, and materials.

Potential Areas for New Research Initiatives

- Basic physical studies in aperture materials, storage materials and heat transfer.
- Performance analysis which includes:
  - — Strategies for integrating passive heating, cooling, and daylighting designs with conventional non-residential building energy systems;
  - — Strategies for reducing or avoiding cooling loads in residential buildings;
  - — Performance characterization of daylighting systems in non-residential buildings;
  - — Analysis of passive cooling technologies; and
  - — Building energy analysis simulations and computer code validations.

Passive and Hybrid Solar Program
Lawnie H. Taylor (202) 252-8103

Photovoltaic Energy Technology

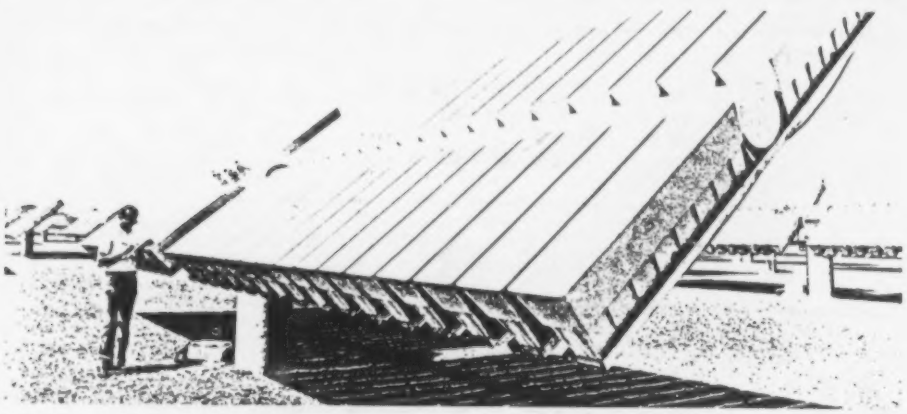
Program Objectives

The DOE Photovoltaic Energy Technology program seeks to advance scientific understanding and to enlarge the technology base needed for the private sector to develop and utilize advanced photovoltaic energy systems. Efforts of this program are focused on increasing the understanding of physical phenomena and defining, analyzing and testing materials, conversion devices and system concepts as well as establishing a technical feasibility of advanced cells and systems. Other primary concerns of this program are to improve sunlight-to-electricity conversion efficiencies, to increase the stability of the semi-conductor materials and conversion devices, to enhance the reliability of components and systems, to seek low-cost materials and processes, and to obtain experimental data on the performance of devices and systems.

Potential Areas for New Research Initiatives

Research on the conversion of sunlight directly into electricity (which involves the motion of free electrons within semi-conductor materials under the stimulation of electromagnetic radiation in the visible and near-visible spectrum) includes theoretical and applied physics, inorganic and organic chemistry, and electronic/electrical and materials engineering. Opportunities include:

- Materials Research (supports research on properties of photovoltaic materials, screening of new materials, material interfaces, reaction kinetics and thermodynamics, defect chemistry, materials stability, etc.).
  - — Research on reaction kinetics and thermodynamics of silane pyrolysis in a particulate silicon media (to determine, for example, if the pyrolysis is a homogeneous, heterogeneous or autocatalytic reaction); chlorosilane formation, disproportionation and pyrolysis reactions.
  - — Basic research and testing of amorphous materials.
    - – Fundamental understanding of glow discharge amorphous silicon-hydrogen.
    - – Deposition techniques such as sputtering and chemical vapor disposition that show promise for improved film properties and capability for large area, uniform deposition with high deposition rates.
    - – Plasmadynamics of large area glow discharges for fabricating thin films of amorphous silicon-hydrogen.
    - – Fundamental properties of other amorphous materials such as amorphous silicon-carbide.
    - – Interfaces between dissimilar amorphous materials such as amorphous silicon-hydrogen with indium tin oxide.
  - — Basic and applied research on crystal silicon.
    - – Basic mechanisms of point, line and area defects in silicon crystals and their effect on semi-conductor characteristics.
    - – Growth mechanisms in silicon sheets that control the presence of dislocations and other structural defects and of chemical impurity clusters.
  - — Research on materials for thin-film polycrystalline cells.
    - – Interface between cadmium-zinc-sulfide and copper-indium-diselenide to reduce interface states and decrease recombination losses.
    - – Improved stoichiometry and crystal perfection by the use of electrochemical deposition techniques, particularly for cadmium telluride.
  - — Research on growth theory for multibandgap materials, new materials for very high efficiency cells and fluorescing materials for luminescent concentrator devices.
    - – Thin film arsenide materials growth for single crystal cells using thin film separation techniques, silicon substrates, etc.
    - – Cascade cell materials growth studies.
    - – Multilayer optical coatings for maximum spectral utilization and research on new contact metallurgy which allows for high current densities at solar radiation concentration ratios up to 1000 suns.
    - – Organic and inorganic luminescent concentrator materials; continuing photochemical research for enhanced energy transfer between luminescent centers; and studying triplet state quenching to inhibit long-term photon damage to organic dye molecules.
  - — Photovoltaic electrochemical mechanisms research.
    - – Semi-conductor materials, electrolyte and redox-couple chemistry and multivalent storage chemistry for photovoltaic electrochemical solar cells with storage capability.
- *Advanced Concepts Research* (understanding the fundamental physical phenomena associated with advanced concepts such as thin films cells, multibandgap cells, luminescent concentrators, etc.).
  - — Advanced cells concepts including analysis of layer thickness, concentration gradients and contact



metallurgy, for improved open circuit voltage, short circuit current and fill factor.
  - — Novel concepts for cascade cell interconnections, such as superlattice, and for diffused connection, laser recrystallization and interface modification.
- *Supporting Research and Measurements* (provides improved techniques for measuring material and device properties, including methodology and interpretation for accelerated lifetime testing, and program management studies.)
  - — Measurement techniques for understanding the stability of thin-film compounds and amorphous cells with emphasis on identification of degradation mechanisms.
  - — Validation of accelerated life test models and techniques for extrapolating silicon photovoltaic module performance to a 20-year service life.
  - — Theoretical models for predicting output characteristics of concentrator array subsystems with feedback to device/module intergration.
  - — Improved methods of examining semi-conductor, metal and insulator interfaces. The rapidly expanding private sector offers increasing opportunities for research and development activity, especially investigations offering near-term applications.

Photovoltaic Energy Technology
Robert Annan (202) 252-1720

Solar Thermal Energy Technology

Program Objectives
The DOE Solar Thermal Energy Technology program seeks basic research and development of materials, processes, components and systems for the generation of thermal, mechanical and electrical power, and for thermochemical or photochemical production of petrochemical substitutes using concentrated solar energy. Efforts of this program are focused on cost and performance improvements and acceptable reliability, durability and safety characteristics.

Potential Areas for New Research Initiatives
- Development of high temperature, high flux concentrating collectors and receivers for the efficient production of process heat and electric power.
- Development of low-cost concentrators utilizing metalized polymeric reflecting surfaces and innovative geometric configurations.
- Identification and engineering of solar-enhanced processes for the production of fuels and chemicals.

Solar Thermal Energy Technology
Frank (Tex) Wilkins (202) 252-1684

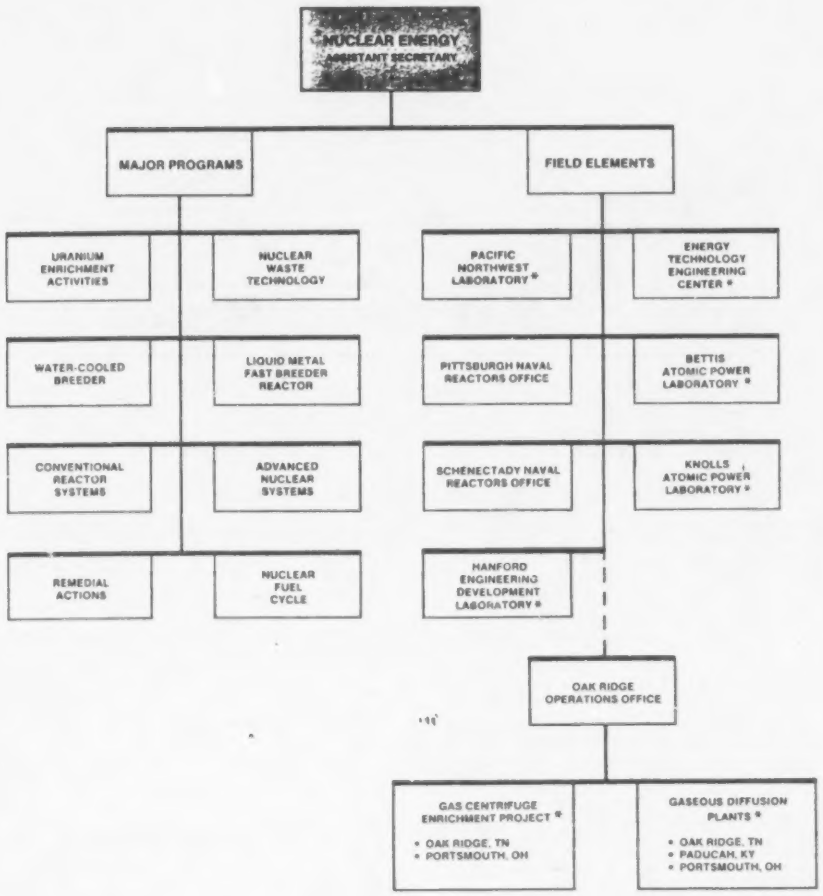
Wind Energy Technology

Program Objectives
The Wind Energy Technology program seeks to provide a technology base that will enable the private sector to develop and utilize wind energy systems.

Potential Areas for New Research Initiatives
- Advanced concepts and research for improving aerodynamic performance and design analysis methods for wind turbines;
- Theory and models for predicting aeroelastic and structural dynamics characteristics;
- High strength, low-cost motor blade materials;
- Ultra-high cycle blade fatigue life prediction methods.

Program Information Contact
Wind Energy Technology
Louis Divone (202) 252-5540

Nuclear Energy

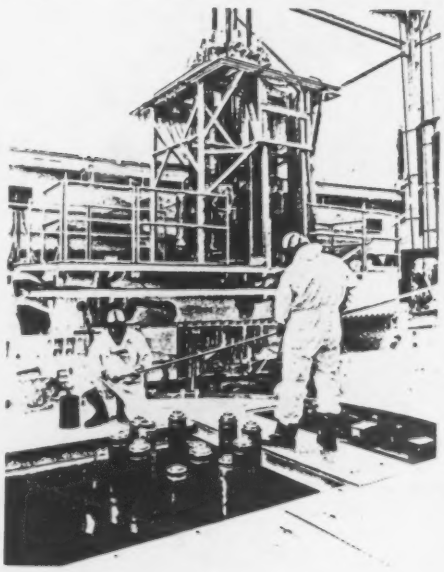


* CONTRACTOR OPERATED FACILITIES

Assistant Secretary for Nuclear Energy

General Description

The Assistant Secretary for Nuclear Energy (NE) is responsible for the administration of nuclear fission power generation and fuel technology, including breeder reactor technology; the evaluation of alternative reactor fuel cycle concepts; development of space nuclear generator systems; uranium enrichment activities, including development of advanced enrichment technology; development of naval nuclear propulsion plants and reactor cores; nuclear waste technology; remedial action program; and nuclear fuel cycle research and development. Much of the Nuclear Energy effort is directed toward technology and engineering development programs which is performed by DOE laboratories and other major industrial contractors. Several programs of potential interest to researchers are discussed on the following pages.



Field Elements

The major test facilities for the Office of Nuclear Energy are located at the Argonne National Laboratory (ANL), and the following program dedicated sites: the Bettis Atomic Power Laboratory, the Energy Technology Engineering Center (ETEC), the Hanford Engineering Development Laboratory (HEDL) and the Knolls Atomic Power Laboratory (KAPL). Existing test facilities are operated and maintained, in support of the plant projects and breeder technology elements of the Liquid Metal Fast Breeder Reactor (LMFBR) program in accordance with technical requirements, priorities, and scheduled needs identified under those elements, consistent with safe, efficient operation and acquisition practices. For further information on these program dedicated facilities, please refer to the summaries at the end of this section.

The field elements of the Breeder Reactor Technology base program are composed of test facilities and contractors which include national laboratories, universities and industry. Test facilities are an essential part of the LMFBR program in that they provide the capability to test systems and components developed under the breeder technology program, as well as prototypes and models of components to be incorporated into plant projects. Through operation of irradiation facilities such as the Fast Flux Test Facility (FFTF) and Experimental Breeder Reactor (EBR II), and operation of large nonnuclear sodium facilities, plant performance information on operation and maintenance is also generated to support plant projects. The Clinch River Breeder Reactor Plant (CRBRP) project office, located at Oak Ridge, Tennessee, is the primary field element for the closeout activities of the CRBRP project.

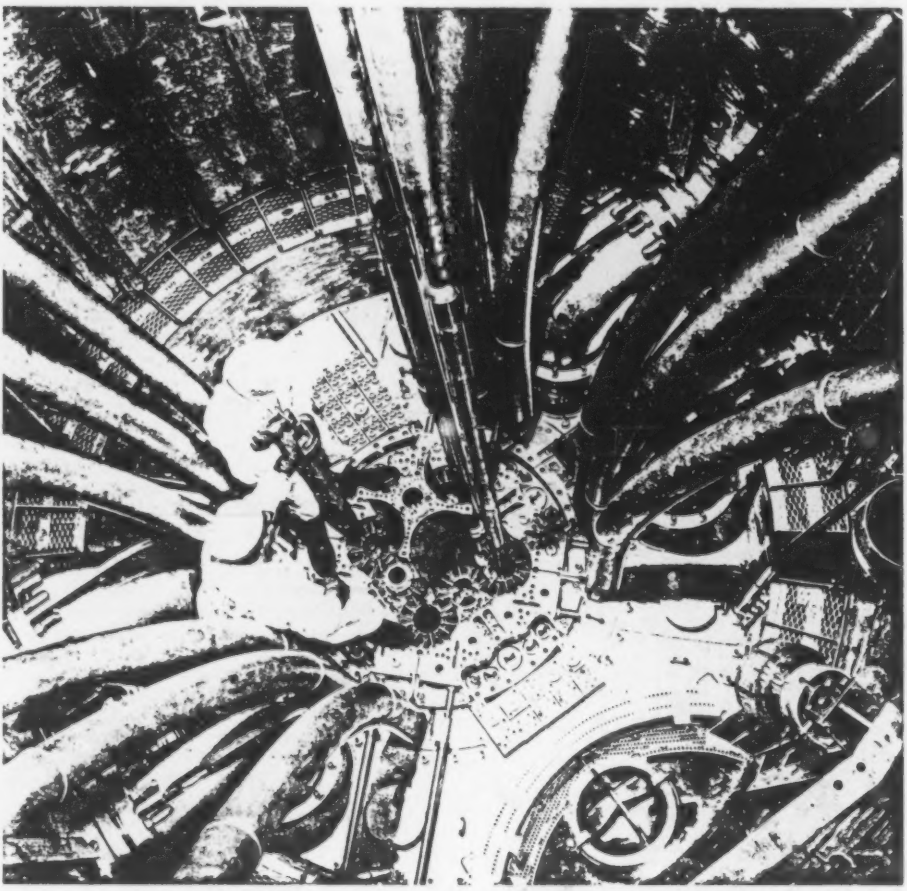
Mission system development work is usually performed by the industrial contractors. Fuel and safety research and development, special metals technology research and development, capsule hardware fabrication, and heat source assembly are done in Government-owned contractor-operated laboratories and plants because these operations depend on the nuclear facilities, equipment, and expertise maintained for nuclear fuel and weapons programs.

Qualification and flight acceptance tests of the isotope space power converter subsystems are supported by the Mound Plant, Miamisburg, Ohio. Iridium blanks fabricated at the Oak Ridge National Laboratory, will be provided to the Mound Plant where the iridium is formed into fuel capsule containers. The Savannah River Plant will manufacture 63-watt thermal pellets of plutonium-238 and encapsulate them into the thermoelectric converter hardware by Mound Plant staff. Safety analyses and safety testing by the Los Alamos National Laboratory will be conducted on representative flight isotope hardware components to assess the safety margin of the system.

Proposal Review Procedures

All unsolicited proposals for submission to the Office of Nuclear Energy should be sent to:

Unsolicited Proposal Coordinator
Reports and Analysis Branch
Procurement and Assistance Management Directorate
U.S. Department of Energy
Washington, D.C. 20585



The proposals will be logged into the DOE proposal system and will be sent to the responsible program official for evaluation. The proposals are generally reviewed by in-house program staff but, in some instances, the program official may have the proposal reviewed by scientists/engineers in the field laboratory facilities. In such cases, the prior written permission of the proposer is obtained. A technical evaluation is prepared by the cognizant program office representative and, based on the evaluation, funding recommendations are made.

The Office of Converter Reactor Systems generally uses a Notice of Program Interest (NPI), to encourage proposal submission for its programs. This notice describes an interest by DOE in innovative approaches to specific problem areas. NPI's are not formal solicitations, but are used instead as a communications device to aid potential proposers in focusing on areas where proposals may be mutually beneficial to DOE programs and the proposer. NPI's are generally published in the *Commerce Business Daily* or the *Federal Register* and are widely distributed.

Advanced Nuclear Systems Programs

Program Objectives
The role of the Advanced Nuclear Systems Program is to respond to Department of Defense (DOD) and National Aeronautics and Space Administration (NASA) requirements for the design, development, and delivery of space nuclear power systems. The program at present

consists of three projects: Static Outer-Planetary Radioisotope Thermoelectric Generator (RTG) project—developing RTG's for NASA Galileo mission to be launched in 1986 and the Space Reactor Development Program—an advanced technology readiness program for both civilian and military missions in the more distant future; and a terrestrial RTG project that is classified.

Program Structure

The Advanced Nuclear Systems program is responsible for the development and delivery of nuclear power sources for U.S. military and civilian space and terrestrial missions and for the assessment/maintenance of these nuclear energy sources consistent with the agency's health and safety requirements. The program consists of three broad elements: Flight Systems Development, Flight Systems Support, and Special Applications.

Flight Systems Development includes the design, development, fabrication, assembly, and test of isotopic space power systems on a revised schedule for the NASA Galileo and International Solar Polar Spacecraft. Also included is the development of a space nuclear reactor power source capable of producing electricity in the 100 Kw(e) power range or above. Another major activity is a technology program aimed at demonstrating a new, light weight, radioisotope thermoelectric generator (RTG) design that takes advantage of improved thermoelectric materials, new fabrication techniques, and new design concepts (MITG).

Flight Systems Support covers fabrication of plutonium fuel necessary for flight spacecraft missions as well as for the safety and environmental efforts. It also includes basic space nuclear power system technology development and support of the flight system program.

Special Applications includes design and integration studies. Activities such as development tests on advanced RTG components aimed at extending power system lifetimes, minimizing personnel exposure operations, and analyses of compact nuclear related studies, assessments and nuclear training programs are also supported.

Program Information Contact
Advanced Nuclear Systems
Earl Wahlquist (301) 353-3795

Converter Reactor Systems

Program Objectives

The Light Water Reactor (LWR) Program, the High Temperature Reactor (HTR) Program, the Advanced Reactor Systems Program, and the Three Mile Island Activities Program make up the elements of Converter Reactor Systems. Programs supported by the Department in the LWR area seek to improve plant safety, reduce occupational exposure to radiation, reduce plant lead times, improve the efficiency of uranium fuel, and enhance converter reactor deployment through institutional, regulatory reform measures. For the HTR Program, the Department will be pursuing design and development activities to support the process steam/cogeneration concept which has been decided upon as the lead plant project. The Advanced Reactor Systems Program has the objective of developing and demonstrating proliferation-resistant reduced enrichment fuels for research and test reactors. Finally, the Department maintains a research program to determine the causes for and safety implications of the accident in 1979 at the Three Mile Island nuclear electric plant in Pennsylvania and to develop recommendations for improving the safety and reliability of all nuclear plants. In 1981, the Department started a program to remove and stabilize, and dispose of all the abnormal waste generated during the accident.

Potential Areas for New Research Initiatives

- Fuel safety technology development;
- LWR water chemistry;
- Education and training of plant operations personnel;
- Advanced instrumentation for powerplants;
- Waste immobilization; and
- Licensing and regulatory reform.

Converter Reactor Systems
Jerry D. Griffith (301) 353-3773

Liquid Metal Fast Breeder Reactor Program

Program Objectives

The Liquid Metal Fast Breeder Reactor Program (LMFBR) is a research, design, and development program to confirm the economics, safety, and reliability of breeder reactor systems in support of the timely and effective integration of these reactors with the current nuclear industry and fuel cycle technology. LMFBR technology is being developed by the base program to solve the long-lead time technical problems before reactor demonstration takes place. At the same time, the Department is pursuing the main-line reactor project developmental efforts, which include the operation of the 400 megawatt (thermal) Fast Flux Test Facility and construction of the Fuels and Materials Examination Facility at Richland, Washington and the advanced Conceptual Design Study of the 1000 megawatt (electrical) Large Scale Prototype Breeder.

Program Structure

The thrust of the Breeder Reactor Systems program is to complete the research and development of breeder reactor technology to the level that is appropriate for transfer to industry. The private sector has the ultimate responsibility for plant investment and commercialization of the technology. The program includes a supporting technology base program, which covers test facility construction and operation technology research and development efforts in reactor fuels, components, physics, and safety. These elements are closely integrated and are directed at breeder powerplant development, focusing on the development of an economically competitive breeder that is inherently safe.

Potential Areas for New Research Initiatives
Methodology, systems, and hardware to:

- Improve plant reliability;
- Reduce plant capital costs;
- Improve fuel performance and breeding; and
- Ensure plant safety.

Program Information Contact
Liquid Metal Fast Breeder Reactor
Earl Wahlquist (301) 353-3795

Nuclear Fuel Cycle

Program Objectives
The Nuclear Fuel Cycle program provides for development and demonstration of advanced technology for reprocessing of irradiated fuels from nuclear power reactors. Primary emphasis of the development and demonstration effort is on the more stringent requirements associated with reprocessing of Fast Breeder Reactor (FBR) fuels, including the higher thermal and radiation burdens, higher fissile content, sodium contamination, and heavier fuel assembly structures. Advanced developments for FBR fuel reprocessing will be available for use by future light water reactor fuel reprocessors. The technical program focuses on development and demonstration of reprocessing technology that will provide for reduced radiation exposure to workers, increased environmental protection, increased reliability, enhanced safeguards, and reduced costs.

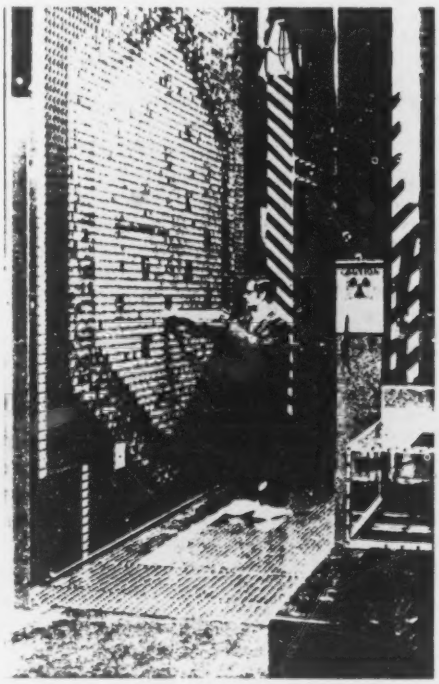
Potential Areas for New Research Initiatives

- Radiation hardening of instrumentation, TV cameras, other electronic equipment.
- Man-machine interface in a nuclear environment, i.e., performance of humans under more complex and sophisticated operating conditions.
- Advanced manipulator development for remote maintenance, i.e., more rugged components, improved instrumentation and controls, force reflection.

Program Information Contact
Nuclear Fuel Cycle
Vicki Barden (301) 353-5019

Nuclear Waste Technology

Program Objectives
The objective of the Nuclear Waste Technology program is to support technology related to the long-term management and disposal of commercial radioactive waste. Included are only those activities under the responsibility of the Assistant Secretary for Nuclear Energy which were previously part of the Commercial Waste Management decision unit and are not covered by the Office of Civilian Radioactive Waste Management under the Nuclear Waste Policy Act of 1982. Specific activities include:(1) assistance to the states to develop regional compacts for the disposal of low-level waste; and (2) development, selection, and demonstration of



waste treatment and solidification processes suitable for disposal in a repository.

Potential Areas for New Research

- Development of improved techniques for low-level waste disposal.
- Development of waste technology to support handling, immobilization and disposal of transuranic and high-level wastes.

Program Information Contact
Nuclear Waste Technology
Joseph A. Coleman (301) 353-4728
(excludes activities under the Nuclear Waste Policy Act of 1982)

Remedial Actions

Program Objectives
The objective of the Remedial Actions program is to treat or stabilize radioactive wastes and perform required decontamination and decommissioning at contaminated DOE and legislatively dictated non-government facilities and sites. The general approach applied to fulfilling this objective is (1) to verify the need for remedial action by conducting radiological surveys of suspected contaminated properties; (2) to define the method of accomplishing required remedial action, based on existing radiological

criteria, by developing engineering options and conducting appropriate National Environmental Policy Act reviews; (3) to carry out the selected remedial action; and (4) to certify completion of the remedial action consistent with existing radiological criteria.

The major problem areas are: (1) formerly utilized sites remedial action program (FUSRAP); (2) remedial action at Grand Junction, Colorado (P.L. 92-314, as amended); (3) uranium mill tailings remedial action program (UMTRAP) for inactive uranium mill tailings (P.L. 95-604); (4) management of certain radioactively contaminated Department facilities declared surplus and resulting principally from civilian nuclear energy programs; and (5) demonstration of the solidification of high-level radioactive wastes at West Valley for final disposal (P.L. 96-368).

Potential Areas for New Research

- Development of new decontamination and decommissioning techniques for contaminated facilities and sites.
- Development of new methods for determining radioactive nuclide transport through various media.
- Development of containment techniques for inactive uranium mill tailings sites to assure no radioactive migration.
- Development of remote sluicing techniques for removal of highly radioactive clay-like sludge from the bottom of High-Level Waste storage tanks.

Program Information Contact

(all except West Valley)

West Valley Demonstration Project
James A. Turi (301) 353-5241

Uranium Enrichment Activities

Program Objectives

The major objective of the Uranium Enrichment Program is to meet the domestic, foreign, and U.S. Government requirements for uranium enrichment services in the most economical, reliable, safe, and environmentally acceptable manner possible.

To assure that this objective continues to be met, the Department of Energy supports development programs to provide cost effective alternatives for replacing existing enriched uranium production capacity by the mid-1990's. Two processes have the potential to meet this criterion and are being actively considered. They are: (1) gas centrifuge separation based on advanced designs, and (2) the Atomic Vapor Laser Isotope Separation technique, which employs finely-tuned, red-orange laser light to separate the uranium isotopes. Research initiatives in the uranium enrichment technical area would focus on, but would not be limited to, projects which would be directly applicable to either development program.

Potential Areas for New Research Initiatives

- Advanced concepts in isotope separation;
- Visible laser electro-optic subsystem and component development;
- Uranium materials science.

Program Information Contact

Uranium Enrichment Activities
Norton Haberman (301) 353-4781

Water Cooled Breeder

Program Objective

The Water Cooled Breeder Program's objective is to develop technology for significantly improving nuclear fuel resource utilization by water cooled nuclear reactors used for electrical power generation. The concept currently under development is a self-sustained breeder reactor cooled and moderated with light water. Successful development of this breeder cycle, including confirmation of breeding, can provide the basic technology to make available for power production about 50 percent of the nation's thorium reserves, a source of energy many times greater than the known fossil fuel reserves.

Potential Areas for New Research Initiatives

Further development of the technologies required for a light water breeder reactor.

Program Information Contact

Water Cooled Breeder
Nicholas R. Schact (703) 557-5550

Program Dedicated Facilities

Bettis Atomic Power Laboratory
Post Office Box 79
West Mifflin, Pennsylvania 15122

A.C. Davis
General Manager

Telephone Number (703) 557-5564

The Bettis Atomic Power Laboratory is devoted exclusively to the Naval Nuclear Propulsion Program and includes three sites. The principal one, the Bettis Site, performs research and development of naval nuclear propulsion plants and carries out the Water Cooled Breeder program. The Shippingport Atomic Power Station, the first commercial nuclear power station, presently contains a Light Water Breeder Reactor. Operated by the Duquesne Light Company, this unique reactor produced electricity for the commercial power grid and is now being defueled. The third site, the Naval Reactors Facility, is located within the Idaho National Engineering Laboratory site. This installation operates three prototype naval reactor plants and a facility for examination of naval reactor cores.

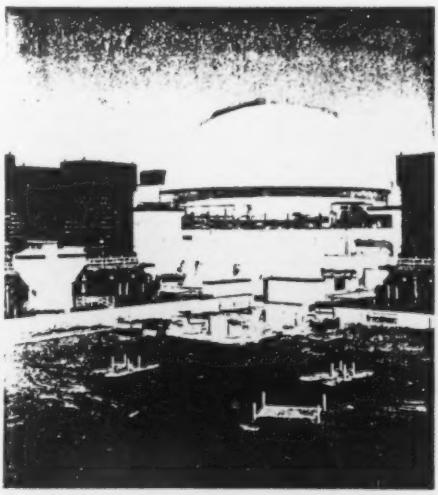
Energy Technology Engineering Center
Post Office Box 1449
Canoga Park, California 91304

H.C. Wieseneck
Vice President and General Manager
Telephone Number: (213) 700-5326

The Energy Technology Engineering Center (ETEC) provides management, engineering, testing, consultation and project monitoring services for a wide range of Department of Energy (DOE) programs. ETEC tests components being developed for the U.S. fast breeder reactor program. Liquid-sodium test facilities are maintained and operated by ETEC for evaluating components such as heat exchangers, steam generators, pumps, valves, piping and instrumentation. In addition to the reactor component testing program, ETEC provides engineering support, technical management and monitoring for a variety of DOE solar heating, cooling and power projects, geothermal power plants and direct use applications, and fossil energy fuel conversion programs.

Hanford Engineering Development Laboratory
Post Office Box 1970
Richland, Washington 99352

John E. Nolan
Director
Telephone Number (509) 376-3915



Fred J. Leitz
General University Activities Contact
Telephone Number (509) 376-3110

The Hanford Engineering Development Laboratory (HEDL) is committed to the development of breeder reactor fuels, materials research, and the development of advanced nuclear power concepts. The 400 MW Fast Flux Test Facility is the most advanced test reactor in the country and is the major HEDL test bed for breeder reactor development. The special materials expertise of the laboratory is also being utilized to support development of special reactor materials for the fusion program. The Fusion Materials Irradiation Test facility is being designed and constructed to support this effort.

Knolls Atomic Power Laboratory
U.S. Department of Energy
Post Office Box 1072

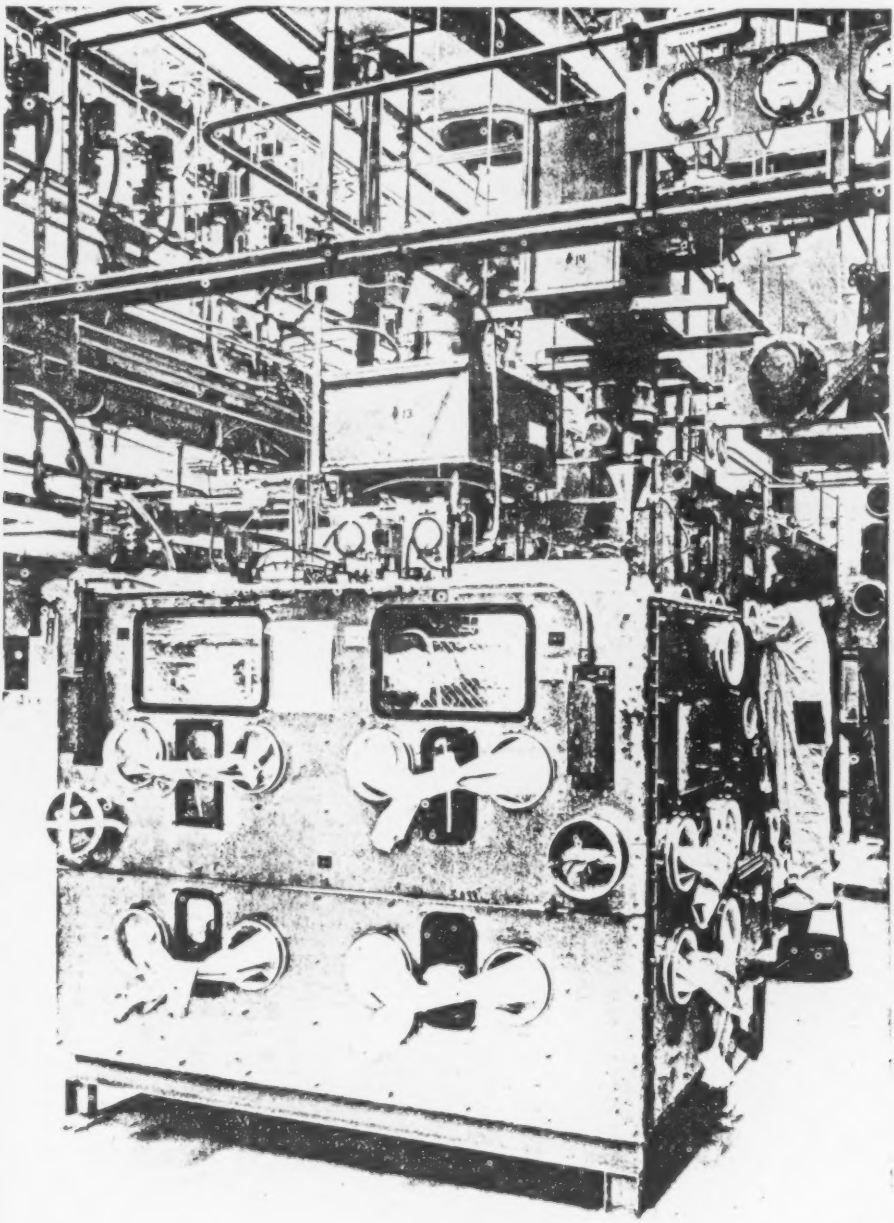
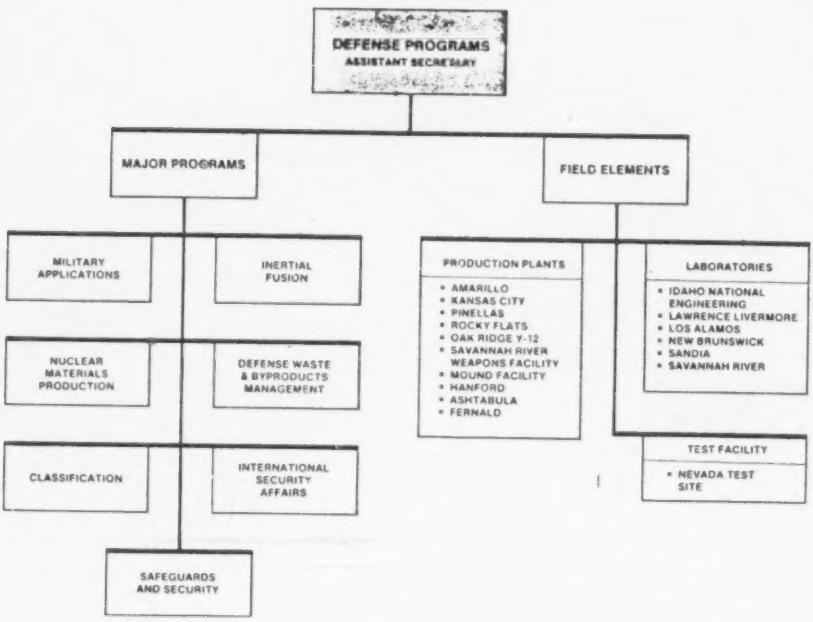
Richard A. Guida
General University Activities Contact
Telephone Number (703) 557-5564

The Knolls Atomic Power Laboratory (KAPL) is devoted exclusively to the Naval Nuclear Propulsion Program, and includes a three sites. The principal one, the Knolls Site, performs research and development of naval nuclear propulsion plants. Also in Schenectady, the Kesselring Site is the location for four prototype plants. The Windsor Site, in Windsor, Connecticut, is the location of a fifth prototype.



57

Defense Programs



Assistant Secretary for Defense Programs

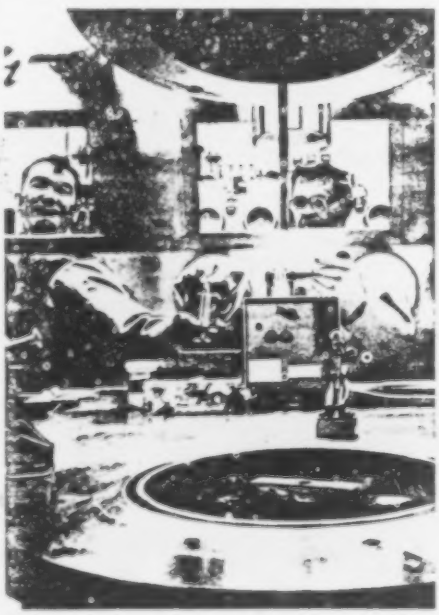
General Description

The Assistant Secretary for Defense Programs manages Department of Energy programs for nuclear weapons research, development, testing, production and surveillance; laser, heavy ion, and particle beam fusion; safeguards and security programs; the international security program; and classification. In addition, the office is responsible for the nuclear materials production and defense nuclear waste programs and exercises overview responsibility for the DOE weapons complex.

There are seven major program offices within Defense Programs. They are the Offices of Military Application, Inertial Fusion, Safeguards and Security, International Security Affairs, Nuclear Materials Production, Defense Waste and Byproducts Management, and Classification.

Field Elements

In addition to the major program offices, the Headquarter's Offices of Policy, Planning and Coordination and Resource Management serve as the DOE focal point on policy and institutional management of assigned field facilities. The Operations Offices play a significant role in the development, production or testing of nuclear weapons. Los Alamos, Lawrence Livermore, and Sandia Laboratories are involved in varying degrees in support of all facets of the weapons program, i.e., design, engineering, test production, and surveillance. The New Brunswick Laboratory supports the security and safeguards program; Savannah River Laboratory is specifically involved in production of nuclear materials. The Mound and Savannah River Weapons Facilities, Amarillo, Kansas City, Pinellas, Rocky Flats, and Y-12 Plants are engaged in the weapons production program. The Savannah River, Hanford, Ashtabula, Fernald and Idaho Chemical Processing Plants constitute a major part of the DOE Nuclear Materials Production Program. The Nevada Test Site is reserved for nuclear test operations.



Proposal Review Procedures

In general, after a proposal has been received in the Office of Defense Programs and has been logged into the DOE procurement system, the proposals are assigned to a field office for technical evaluation. The evaluation and budget constraints determine whether the proposal is accepted or declined. If accepted, the normal administrative process for contract negotiations takes about six months.

The Office of Inertial Fusion, Defense Programs, however, uses a variation of this procedure. Unsolicited proposals intended for review by the Office of Inertial Fusion should be submitted directly to the Nevada Operations Office as follows:

Mr. Rex Purcell
U.S. Department of Energy
Nevada Operations Office
Post Office Box 14100
Las Vegas, Nevada 89114
Telephone: (702) 295-0969

The Nevada Operations Office accepts the proposals and determines which lead laboratory should provide a technical review. The proposal is sent to the appropriate laboratory for technical review and a recommendation is made as to whether or not the proposal has technical merit. The Nevada Operations Office makes a decision based on that recommendation, and other factors (such as program priorities and availability of funds). If a proposal is accepted, the Nevada Operations Office negotiates, awards, and administers the necessary Inertial Fusion Program contract. Technical monitoring is provided by the cognizant lead laboratory.

Program Information Contact

General Information
A. Bryan Siebert (301) 353-4227

Defense Waste and Byproducts Management

Program Objectives
The objective of the defense nuclear waste management program is to assure that existing and future nuclear waste from DOE program activities can be isolated from the biosphere and pose no significant threat to public health and safety. To implement this objective, the DOE program focuses on the development of technology and the processes necessary for long-term disposal. This program also provides for the decontamination and decommissioning of facilities that are surplus to DOE activities.

Potential Areas for New Research Initiatives

Transuranic Waste
- Mechanism(s) for immobilizing transuranic waste (TRU) elements.
- Modeling TRU element leaching from waste.
- Rate modeling for accelerated leach testing. (Short-term test to predict long-term TRU leach rate behavior).

High-Level Waste
- Waste form performance in a repository including mechanisms for immobilizing high-level waste.
- Radiation damage.
- The mechanism(s) of glass leaching.
- Fracture behavior of nuclear waste forms e.g., glass.
- Devitrification behavior in glass.

Byproducts and Beneficial Uses
- Food preservation/disinfestation by irradiation
- Human factors regarding use of tritium and krypton lights

Low-Level Waste
- Improving stabilization of shallow land burial grounds used in disposal of low-level radioactive wastes

Program Information Contact
Defense Waste and Byproducts Management
James C. Landers (301) 353-3506

Inertial Fusion

Program Objective
As part of the weapons program effort, the goal of the inertial fusion program is to determine the potential of inertial fusion for application to weapons technology and to energy production. The next major objective of the technical program to accomplish this goal is to understand driver/target interactions in the range of driver energies obtainable with the following experimental facilities now being built:
- ANTARES carbon dioxide laser at Los Alamos National Laboratory, Los Alamos, New Mexico;
- NOVA glass laser system at Lawrence Livermore National Laboratory, Livermore, California;
- Particle Beam Fusion Accelerator (PBFA) II at Sandia National Laboratories, Albuquerque, New Mexico.

National Laser Users Facility
The University of Rochester operates the National Laser Users Facility at which experiments in inertial fusion or other scientific fields can be performed by university, industrial, or government research teams. The DOE encourages anyone interested in conducting an experiment at the National Laser Users Facility to forward proposals to:

Mr. Rex Purcell
U.S. Department of Energy
Nevada Operations Office
Post Office Box 14100
Las Vegas, Nevada 89114
Telephone: (702) 295-0969

Additional information on the National Laser Users Facility may be requested from:

Dr. Tom Bristow
Executive Secretary
National Laser Users Facility
University of Rochester
Laboratory for Laser Energetics
250 East River Road
Rochester, New York 14623
Telephone: (716) 275-2074

or from the *User's Guide to DOE Facilities* (DOE/ER-0174).

Problem Areas Requiring Additional Research
- Laser/matter interaction;
- Particle beam generation and transport;
- Plasma diagnostics; and
- Target fabrication

Program Information Contact
Inertial Fusion
Dr. R.L. Schriever (301) 353-3463

Military Applications

Program Objectives

The overall objectives for the weapons program are to:

1. Insure adequate and timely nuclear weapon design options for national security;
2. Produce new nuclear weapons as requested by the Department of Defense and approved by the President;
3. Provide lifetime surveillance and maintenance of the existing weapons stockpile to assure a constant state of high readiness and reliability; and
4. Advance and transfer technology applicable to other national security and energy programs.

The highly complex and classified nature of the weapons program mission precludes any further expansion of direct university involvement in the program beyond the levels currently projected. However, the major operating contractors involved in the program do support subcontract efforts at universities consistent with program priorities, university capabilities, and funding availabilities.

Program Information Contact
Military Applications
Bruce A. Cooper (301) 353-3374

Nuclear Materials Production

Program Objectives

The goal of the Materials Production program is to provide nuclear materials to meet near-term national defense and nondefense requirements in a safe, environmentally acceptable manner. In addition, Materials Production sustains a base production program capable of meeting long-term nuclear materials production requirements consistent with the annual Presidential Nuclear Weapons Stockpile Memorandum and the annual DOE Materials Management Plan.

Potential Areas of Research Initiatives

- Processing of nuclear materials
- Decision support system
- Robotics for remote operations
- Special isotopes separation
- Assessment of the impacts of plant operations on the environment
- Reactor safety

Program Information Contact
Nuclear Materials Production
Robert J. Galbo (301) 353-3982

Safeguards and Security

Program Objective

The Office of Safeguards and Security is responsible for coordination of DOE safeguards and security efforts to protect special nuclear materials, nuclear weapons, all classified activities, and DOE facilities. The Office develops, tests, evaluates and assists in the implementation of safeguards systems that incorporate physical protection, material control and material accountability into facility-wide integrated safeguards systems for each installation. The New Brunswick Laboratory supports this office through research on the security and safeguards of nuclear materials.

Potential Areas of Research Initiatives

- Safeguards activities;
- Security activities;
- Technology activities; and
- International activities.

Program Information Contact
Safeguards and Security

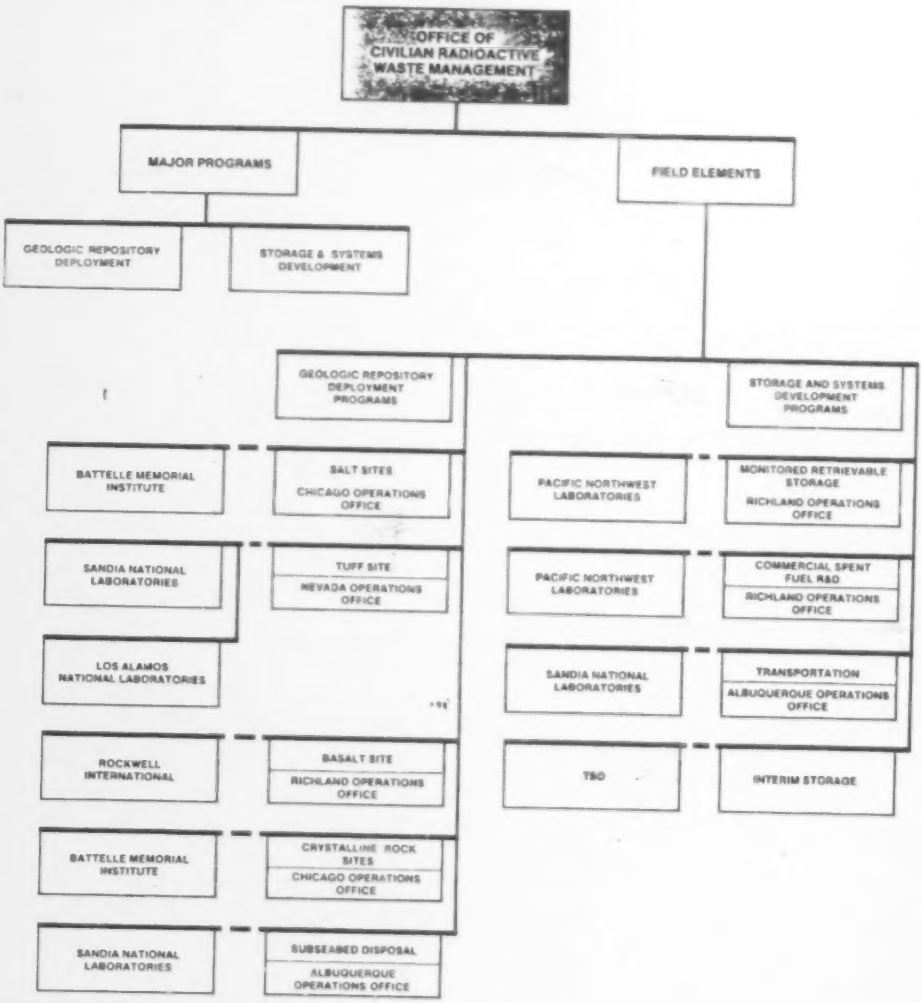
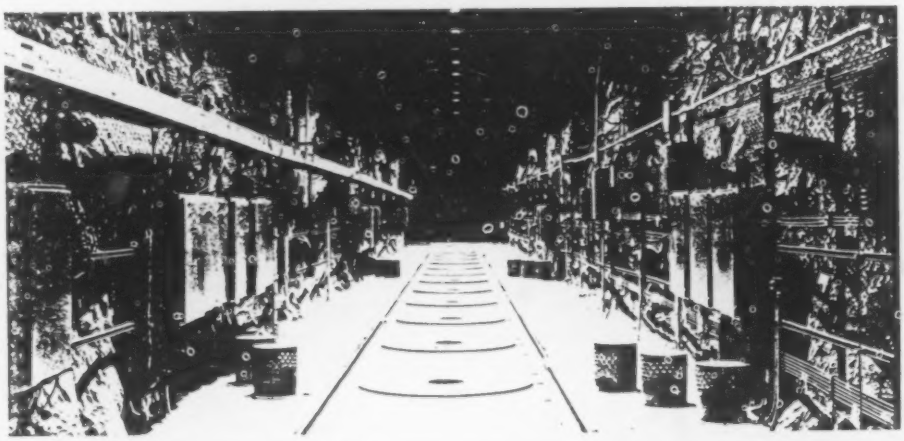
Civilian Radioactive Waste Management



Office of Civilian Radioactive Waste Management



General Description
Section 304(a) of the Nuclear Waste Policy Act of 1982, P.L. 97-425, establishes within the Department of Energy an Office of Civilian Radioactive Waste Management (OCRWM) to focus on research and development leading to the disposal of radioactive wastes. Major responsibilities of the office include: geologic repository activities; storage and systems development activities; and general management and support of the programs and their relationships with other institutions.

The Director of OCRWM provides overall policy recommendations to the Secretary and policy guidance to all elements of the office including to the field project offices.

Field Elements
OCRWM provides policy guidance, general program direction, and overall technical review for the major programs, while field project offices and contractors (as illustrated on the preceding page under "Field Elements") are responsible for the execution of programs and management of specific projects.

Proposal Review Procedures

- **Unsolicited Proposals**
  Proposals submitted to DOE are logged in at a central point in the DOE Headquarters Procurement Office. A written technical evaluation is prepared by the cognizant program office representative and, on the basis of the evaluation, negotiations are initiated or the proposal is officially rejected. Technical work efforts may also be proposed directly to the major technical management center contractor.

Geologic Repository Deployment

Program Objectives
The long-term goal of the geologic repository activity is the construction of one or more repositories for the permanent disposal of high-level radioactive waste and spent nuclear fuel in a manner that fully protects the public health/safety and the environment.*

The principal functions of this program are to locate, design, construct, operate, and decommission radioactive waste disposal facilities. The program is responsible for screening and characterizing potential geologic repository sites; recommending sites; conducting in-situ tests within exploratory shafts; designing a test and evaluation facility; and managing the R&D of disposal technology for both repositories.

Subseabed disposal is the only alternative means of disposal to mined geologic repositories currently being funded by DOE. This method is being undertaken as a national and international enterprise. The major objectives of this activity are to determine the feasibility of burying high-level radioactive waste in stable clay sediments of the deep ocean; cooperate with other nations in the

assessment of subseabed disposal; and, if the concept proves feasible, retain this as an alternative method of nuclear waste disposal.

Potential Areas for New Research Initiatives

- Sorption of radionuclides on geologic media;
- Leaching of waste forms in ground waters;
- Interactions among materials of the waste package, host rocks, and ground waters;
- Fracture flow in geologic media;
- Radiation effects on repository containment;
- Solubility of radionuclides in ground waters;
- Flow and transport in unsaturated media;
- Measurement of hydrologic parameters in low permeability rocks;
- Reliability of stress measurements under expected repository conditions;
- Radiation effects on deep-sea organisms;
- Development of deep ocean monitoring techniques to measure radionuclide transport and chemical effects in sediments; and
- Identification and characterization of the life cycle of mid-water organisms (below 1000 meters).

Geologic Repository Deployment
J. William Bennett (301) 353-4286

*The reader should also note that longer-range research relative to nuclear waste isolation is supported in the Basic Energy Sciences Program of the Office of Energy Research.

Storage and Systems Development

Program Objectives

The role of the Office of Storage and Systems Development is to implement both interim and long-term storage activities. The program is responsible for waste packaging, handling, transportation and storage technologies, equipment, and facilities for radioactive waste. Major project activities include: monitored retrievable storage (MRS) facilities for long-term storage as a backup capability for mined geologic repositories; conducting international cooperation programs; evaluating integrated systems for packaging and transportation of radioactive wastes; and providing Federal interim storage (FIS) facilities, if needed. The Office also encourages, through a joint demonstration program and R&D efforts, civilian "at-reactor" storage of spent nuclear fuel and assists in licensing various storage options.

The major objectives of this effort are:

- To assure that a safe, environmentally acceptable, and cost-effective transportation system is available to support each of the activities or facilities called for by the Nuclear Waste Policy Act;
- To maximize the efficiency and flexibility of operations required to manage nuclear waste from any of its sources to the final repository;
- To encourage and expedite the efficient use of existing storage facilities and the addition of new "at-reactor" capacity through:
  - — A cooperative demonstration program with the private sector to demonstrate spent fuel rod consolidation in existing water basins;
  - — A cooperative demonstration program with the private sector to develop dry storage technologies that NRC can generically approve;
  - — Consultative and technical assistance to utilities on a cost-shared basis in anticipation of NRC licensing of on-site storage technologies; and

Energy Information Administration

General Information

The Energy Information Administration (EIA) develops and maintains a credible and consistent base of energy information which is made available to the Executive Branch, Congress, state governments, industry and the general public. EIA provides energy data, analysis, and information processing support to the other Department of Energy offices, prepares energy analysis and projections on a regularly scheduled basis (as well as for special purposes) and supports Departmental contingency planning and emergency operations.

EIA also maintains the National Energy Information Center (NEIC). The NEIC edits manuscripts and prepares graphics for EIA publications and distributes all EIA products. These products include: data publications, interpretive reports, information directories, computer tapes for public use, microfiche, and EIA press releases/fact sheets. The NEIC also manages the EIA "Family of Publications" program, under which EIA publications are classified and designed according to energy source and metadata groupings. In 1983, NEIC answered more than 75,000 inquiries about energy matters, about half of them from the business community.

Office of Minority Economic Impact

General Information

The Director of the Office of Minority Economic Impact advises the Secretary on the effects of energy policies, regulations and other actions of the Department and its components on minorities, minority business enterprises and minority educational institutions; on ways to ensure that minorities are afforded the opportunity to participate fully in energy programs of the Department; and on the implementation of the Department's support of research and related programs for the Historically Black Colleges and Universities pursuant to Executive Order 12320.

In carrying out these responsibilities, the Office formulates and manages a research program with the assistance of the Energy Information Administration and other Federal agencies, as appropriate. Such research is focused on determining the effects, including the socio-economic and environmental impact of national energy programs and policies on minorities. The research evaluates and analyzes data to determine minority energy consumption and usage patterns, and evaluates the percentage of disposable income spent by minorities on energy compared to national usage patterns, identifies how programs, policies and actions of the Department effect minority energy consumption and usage patterns.

and determines employment potential and minority business opportunities for minorities in specific segments of the energy industry.

The Office formulates programs to provide management, technical, and financial assistance to minority businesses, educational institutions, and development organizations to enable them to participate in the Department's research or other program activities; and to establish or expand energy-related business opportunities in minority communities. The Office also provides outreach and liaison to minority educational institutions to provide them with information on the Department's programs, policies, and research activities.

It should also be noted that the Office of Minority Economic Impact, pursuant to Section 211(e)(1) of Public Law 95-619 and 10 CFR Part 800, has authority to issue loans to minority business enterprises to assist them by financing up to 75 percent of the costs incurred in preparing bids or proposals seeking DOE contracts or assistance. Information regarding loan availability, eligibility criteria, and application procedures may be obtained from:

Office of Small and Disadvantaged Business Utilization (OSDBU)

General Information

The Office of Small and Disadvantaged Business Utilization is responsible for policy, plans and oversight for execution of DOE functions relating to preference programs for small businesses, minority businesses, other businesses owned by disadvantaged persons, women-owned businesses and labor surplus area firms. The Office provides functional supervision and oversight of DOE personnel as they perform duties relating to these programs. The programs are DOE-wide and are achieved under the executive direction of the Secretary and in functional coordination with the Director of Procurement and Assistance Management.

Some of the specific functions of the Office are:

- Formulates, recommends and monitors implementation of policy for the Department's small business program, disadvantaged business program, women-owned business program, and the labor surplus area.
- Ensures effective implementation of the Department's goals and plans for the preference programs and monitors the activities of the Department's buying offices relating to such plans.
- Ensures that all contracts, solicitations, and subcontracts over $500,000 (or $1 million for public facility construction) include the mandatory plans, goals and/or clauses, unless exempted by law.
- Coordinates the preparation of and recommends Secretarial approval of DOE goals in small, disadvantaged, women-owned business enterprises and labor surplus area business utilization.
- Establishes and maintains outreach liaison contacts with the small business, disadvantaged business and women-owned business communities to provide a flow of information regarding the DOE socio-economic procurement programs and to encourage participation in those programs.
- Reviews, evaluates and reports to the Secretary on the performance of all DOE organizational units in accomplishing preference program procurement goals.
- Counsels small business, disadvantaged business, labor surplus area and women-owned business firms on doing business with DOE.
- Provides necessary support to the Program Manager for the Small Business Innovation Research Program.

National security is the principal mission of the Albuquerque Operations Office (AL) which operates an extensive weapons laboratory and production complex from Florida to California; supervises six area and two support offices; administers two National Laboratories, (Los Alamos National Laboratory and Sandia National Laboratories) five weapons production plants (Rocky Flats, Pinellas, Pantex, Kansas City and Mound), the weapons production facilities at Oak Ridge and Savannah River, and the operation of the Inhalation Toxicology Research Institute, Ross Aviation, and the National Atomic Museum on Kirtland Air Force Base-East at Albuquerque. Major assignments include field coordination and direction of weapons research, development and production; organization and operation of a system for safe-secure transport of all government-owned special nuclear material of strategic quantities; program execution and project management associated with assigned energy research, development and demonstration activities; coordination and administration of nuclear test detection activities; reimbursable assistance to local, state, Federal and foreign governments and the private sector; maintenance of radiological assistance, nuclear weapons accident response capabilities; administration of waste isolation pilot plant project and the uranium mill tailings remedial actions project; and establishment of working relationships with many state, university and regional energy organizations.

The Chicago Operations Office (CH) was intimately involved in the design, engineering, and construction of nuclear power facilities in the 1950's and 1960's as well as the development and demonstration of new energy technologies. CH manages the operations and institutional resources of a broad range of multi-program and single purpose facilities. It also provides acquisitions and assistance, engineering, and other technical support for program and project managers in Headquarters and independently manages assigned projects and energy research and development programs.

Current Chicago Operations assignments include key elements of the liquid metal fast breeder reactor (LMFBR) base technology program, the salt and crystalline rock projects in the Civilian Nuclear Waste Management Program, magnetic confinement fusion R&D and test facility activities, magnetohydrodynamic projects and test facility activities, conservation and renewable energy technology projects, and monitoring of the Federal loan guarantee for the Great Plains Coal Gasification Project.

Laboratories and facilities managed by the Chicago Operations Office include: Argonne National Laboratory, Brookhaven National Laboratory, Ames Laboratory, Princeton Plasma Physics Laboratory, Fermi National Accelerator Laboratory, Bates Linear Accelerator Facility, Environmental Measurements Laboratory, New Brunswick Laboratory, Notre Dame Radiation Laboratory, Radiobiology Laboratory at the University of Utah, Michigan State University (MSU)/DOE Plant Research Laboratory, University of Rochester Biomedical Laboratory and the Solar Energy Research Institute. CH also administers and manages financial instruments in over 200 universities and more than 500 businesses, industries, non-profit organizations, and state and local governments.

The Idaho Operations Office (ID) was established to administer the National Reactor Testing Station, an isolated site for testing various nuclear reactors and for associated support facilities. The site was renamed Idaho National Engineering Laboratory (INEL) in 1974 to better reflect the engineering and development assignments and expanding operations of nuclear and nonnuclear energy programs. INEL's principal mission is to support DOE in its defense-related nuclear materials production and

nuclear waste management programs. Additionally, INEL works to develop economic energy resources by applying engineering and scientific expertise to the agency's research and development programs which include nuclear energy, geothermal and advanced energy sources, environment and safety, and national security applications. ID is responsible at the INEL for operating the Radiological and Environmental Sciences Laboratory, which provides chemistry, dosimetry and environmental monitoring for all on-site activities; supporting the Nuclear Regulatory Commission's Region IV Office of Inspection and Enforcement Division; and administering the National Environmental Research Park. In addition, ID staff are located in Butte, Montana (administering the Magnetohydrodynamic Component Development and Integration Facility); in Grand Junction, Colorado (administering the Remedial Action Program involving mill tailings and support for the National Waste Storage Program); in Denver, Colorado (administering awards and grants in programs such as the state and local energy conservation programs); in West Valley, New York, (administering the Remedial Action Program at West Valley); and in Harrisburg, Pennsylvania, Three Mile Island Site Office (administering INEL's support role in cleanup of the Three Mile Island Unit-2 accident).

Nevada Operations Office

The Nevada Operations Office (NV) was established by the U.S. Atomic Energy Commission and assumed responsibilities for programs at the Nevada Test Site (NTS). The NTS, located 65 miles northwest of Las Vegas, was chosen as a continental proving ground in 1950 to reduce the expense and logistic problems of testing in the Pacific. It is an integral part of NV and does not operate as a separate entity. The primary mission of NTS is to provide a remote, secure facility for the safe conduct of underground nuclear testing in support of national defense programs. Over the years of operation at NTS, NV contractors have developed unique expertise in such fields as drilling, mining, and down-hole diagnostics in support of the weapons development laboratories and the Department of Defense. Additionally, use of the site has been expanded to include many other programs and projects, for example: waste mangement; biological and medical experiments to study plant and animal life in a radiation environment; geologic, hydrologic, and seismic investigations; and development of applications of nuclear explosives in science and industry.

NV is responsible for conducting all U.S. nuclear tests. Other program responsibilities assumed by NV and its contractors include maintaining a readiness base at Johnston Island to resume testing in the Pacific Ocean area, development of geothermal and hydrocarbon natural resources, fuel conservation, and program and contract management of various programs assigned by Headquarters.

The Oak Ridge Operations Office (OR) was originally established under the U.S. Atomic Energy Commission during the Manhattan Project of World War II. Major programs and projects at Oak Ridge Operations Office are the production of nuclear weapon components in support of national defense programs; the production of enriched uranium for defense requirements and for fueling nuclear power plants in the U.S. and abroad (the enriching capacity is being expanded at present, both by the upgrade of the gaseous diffusion process and the development of gas centrifuge and laser isotope separation technologies); the processing of uranium feed materials and related production of uranium fuel cores for the Agency's plutonium production reactors; management of the Department's Strategic Petroleum Reserve; closeout of the Clinch River Breeder Reactor Project; and extensive energy research and development. OR administers the Oak Ridge National Laboratory; Oak Ridge Associated Universities; the Ashtabula Extrusion, Fernald Feed Materials and Y-12 Plants; Oak Ridge, Paducah and Portsmouth Gaseous Diffusion Plants; and the Center for Energy and Environment Research located at the University of Puerto Rico.

The Richland Operations Office (RL) was established as the Manhattan Project Plutonium Production Facility. RL is responsible for: management of the 570-square mile Hanford Site, at which a broad range of nuclear and nonnuclear energy programs are conducted under all agency program Secretarial Offices; continuing operation of nuclear production, chemical processing and waste management programs, including interim storage and ultimate disposition of high-level radioactive wastes; management of advanced reactor development programs; providing program management and overview, budgetary

direction, contract management, and administrative and policy guidance to eight operating and support service contractors; and management of facilities (Hanford Engineering Development Laboratory, Pacific Northwest Laboratory and Hanford Production Operations) and site services. RL supports the local Joint Center for Graduate Study, which provides educational opportunities to agency and contractor staff; contracts with NORCUS, a consortium of about 50 universities which administers a University-Laboratory Cooperative program; participates in the Used Energy-Related Equipment Grant program for universities; and contracts for energy-related research at all major northwestern universities.

San Francisco Operations Office

The mission of the San Francisco Operations Office (SAN) is to execute defense and energy-related programs and to provide input to program development and policy formulation. SAN is responsible for the management, coordination, and support of programs and projects involving weapons research and development, basic research, and R&D in all energy technologies. This includes the administration of the operation of seven laboratory and engineering facilities including two major national laboratories. These facilities are the Lawrence Berkeley Laboratory, the Lawrence Livermore National Laboratory, Stanford Linear Accelerator Center, the Energy Technology Engineering Center, Laboratory for Energy-Related Health Research, Laboratory of Biomedical and Environmental Sciences and the Laboratory of Radiobiology and Environmental Health. Field construction management of major technical facilities is another primary functional responsibility. Examples of major projects include the Mirror Fusion Test Facility, designed to test the Tandem Mirror fusion concept, and the NOVA High Energy Laser Facility for weapons physics and fusion energy research.

Savannah River Operations Office
P.O. Box A

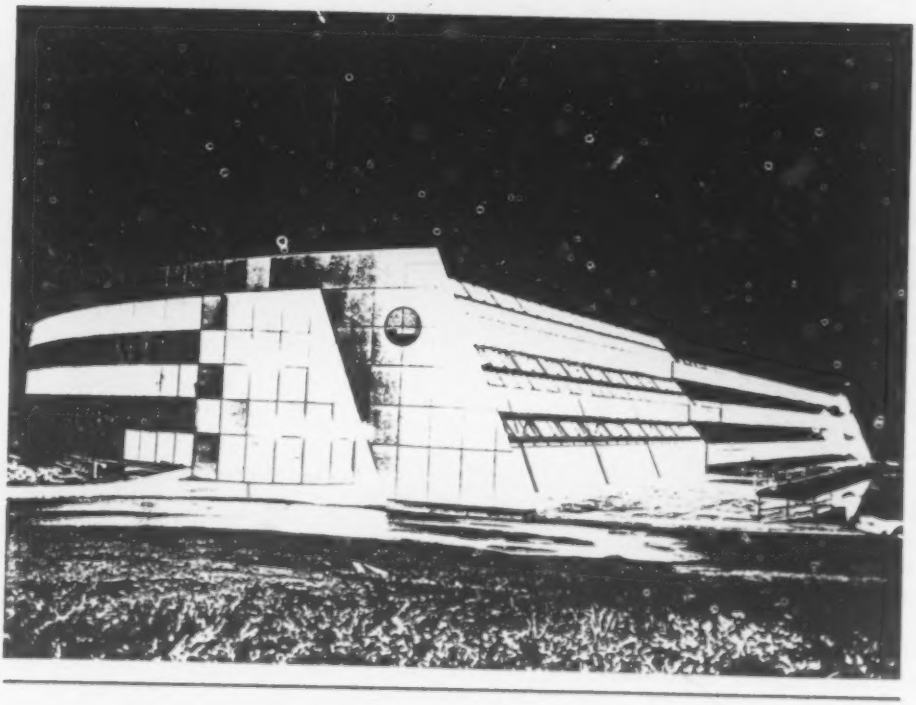
The Savannah River Operations Office (SR) is one of the key installations in the special nuclear materials production and research program in the Department, responsible for production of nuclear materials for national defense, and related environmental research activities. It is responsible for design, construction, operation, and maintenance of a multibillion dollar industrial facility; the program for immobilization and subsequent permanent storage of Savannah River Plant's high-level, liquid radioactive waste; continuing high-level radiological waste management; design, construction and operation of a facility to provide a second source of fuel materials for Naval Nuclear Propulsion Systems; nuclear production reactor operation and safety; chemical reprocessing technology; and studies of the environmental effects of nuclear and industrial operations. The entire site (300 square miles) was designated as the Nation's first National Environmental Research Park in 1972. The laboratories and plants administered by the Savannah River Operations Office are the Savannah River Laboratory, the Savannah River Ecology Laboratory, the Savannah River Plant, the Savannah River Weapons Facility and the Savannah River Forest Station.



Part III
Field Laboratories

Multiprogram Laboratories

The multiprogram laboratories conduct high quality, nationally important basic research and applied research and development that, because of its nature, is more appropriately undertaken by a Federal laboratory than by universities or industry. In fundamental research, the laboratories, therefore, focus on scientific areas of excellence that require large, capital-intensive experimental facilities, or that need sustained effort over periods of many years. In applied research, the focus is on nuclear weapons and defense-related activities, development of energy technologies involving large uncertainties and lead times, or important energy-related environmental factors. The laboratories also maintain for the Government the capability to provide independent scientific advice in their areas of expertise.

These responsibilities require the maintenance of broad multidisciplinary scientific capabilities in the laboratories and the conduct of research and development supporting a technology base appropriate to each laboratory's missions. These capabilities are applied to national problems that are generally between the interests and capabilities of both the university and industrial sectors, and that are of sufficient importance, size, term, and complexity to benefit from and effectively use the laboratories' unique mix of skills and facilities. The laboratories also work with the scientific and technical community, where feasible and beneficial, to achieve effective utilization of their unique research facilities, to aid in education of scientists and engineers, and to enhance the transfer of technology to the public and private sectors.

In all, there are nine DOE multiprogram laboratories. The primary mission of the three weapons laboratories (Lawrence Livermore, Los Alamos and Sandia) is focused on national security. The six other laboratories carry out research and development for all DOE programs (Argonne, Brookhaven, Idaho, Lawrence Berkeley, Oak Ridge, and Pacific Northwest). Each of the multiprogram laboratories is discussed briefly in the following paragraphs. For more detailed information regarding the research facilities at the multiprogram laboratories, also refer to *DOE Research and Development Field Facilities* (DOE/ER-0029) and/or the *User's Guide to DOE Facilities* (DOE/ER-0174).

Argonne National Laboratory (ANL) is operated for DOE by the University of Chicago under the administrative management of the Chicago Operations Office.

ANL provides advanced nuclear technology research and development support to the breeder and other advanced reactor programs, and maintains a substantial, diversified capability in physical and biological sciences. Work in nuclear fusion is focused on blanket technology and materials research. In basic research, a multidisciplinary effort in chemistry, nuclear physics, high energy physics and material research is carried out. Efforts in the fossil area center on advanced process development, the materials technology, and instrumentation and controls systems engineering.

Argonne National Laboratory sponsors a variety of programs providing opportunities for student-laboratory staff interaction and is a major participant in the Department's University/Laboratory Cooperative Program. ANL annually provides research appointments to faculty, graduate and undergraduate students for summer and academic year work in the basic physical and life sciences, mathematics, computer science, and engineering, as well as in a variety of applied research programs relating to coal, conservation, environmental impact and technology, fission, fusion and solar energy.

Brookhaven National Laboratory (BNL) is operated for DOE by Associated Universities, Inc., under the administrative management of the Chicago Operations Office.

The major roles of the BNL are to conceive, construct and operate complex large research facilities, which are used to study the fundamental properties of matter and are shared with university and industrial communities (e.g. the National Synchrotron Light Source and the Alternating Gradient Synchrotron). Major disciplinary strength is found in the areas of high energy, nuclear and solid state physics, chemistry, and biology. Biological

and medical programs include studies of the effects of radiation and of chemical substances involved in the production and use of energy. Applied research programs are undertaken, often in conjunction with university or industrial cooperators, when the unique expertise or facilities available at the Laboratory are needed for the success of the mission.

Brookhaven's participation in the University Laboratory Cooperative Program focuses mainly on opportunities for highly qualified undergraduate students in such areas as the basic sciences, engineering, medicine and the environment. BNL also carries out a cooperative program with several Historically Black Colleges to help increase minority graduate study in the sciences and engineering.

Idaho National Engineering Laboratory (INEL) is operated for DOE by EG&G Idaho, Inc. and Westinghouse Idaho Nuclear Company, Inc., under the administrative management of the Idaho Operations Office.

Effort at this multiprogram laboratory is predominantly nuclear related. INEL missions include spent nuclear fuel reprocessing and recovery of nuclear fuel from several test reactors, the nuclear naval fleet, and other nuclear noncommercial type reactors, as well as processing of liquid waste into calcine form for intermediate storage; operations of a radioactive waste management complex for storage and disposal of low-level waste; investigating the safety of water cooled reactors, principally for the Nuclear Regulatory Commission; operations of the Advanced Test Reactor (ATR) and its experimental materials testing program; functioning as a primary laboratory for fusion reactor safety research; supporting DOE's non-nuclear energy research development programs such as geothermal and industrial conservation, utilizing the newly completed Idaho Laboratory Facility for non-nuclear research and testing; supporting priority defense and civilian nuclear power research and development efforts that are sited at the INEL but are the responsibility of other laboratories; supporting the Three Mile Island (TMI) Technical Information and examination program at the TMI reactor site and at INEL.

Lawrence Berkeley Laboratory (LBL) is operated for DOE by the University of California under the administrative management of the San Francisco Operations Office.

LBL conceives, develops, constructs and operates large, complex research facilities which are shared with university and industrial scientific communities (e.g., Bevalac and Super HILAC). The laboratory capitalizes on its co-location with the University of California to provide a broad range and flexible pool of scientific talent for research and advanced development; with major research programs in high-energy physics, nuclear physics, basic energy sciences, conservation and solar energy, coal research, inertial confinement fusion, geochemistry, computer science and mathematics.

Over 500 resident graduate students conduct thesis research at the Laboratory, and many more use LBL facilities or perform collaborative research. Participation in DOE-supported energy research programs at LBL provides these students with skills in high demand by energy industries.

The Lawrence Livermore National Laboratory (LLNL) is operated for DOE by the University of California under the administrative management of the San Francisco Operations Office.

The mission of LLNL is to function as a national resource of scientific and technical capability for the nation's nuclear weapons program and, as appropriate, for other programs of national interest. The Laboratory's primary role is to perform the research, development and testing associated with the nuclear design aspects of all phases of the nuclear weapon life cycle and perform associated national security related tasks. A corollary role is to address other important national problems meeting the following criteria: synergism with the weapons program; sufficient size, importance, and complexity to make effective use of significant or unique laboratory capabilities; and relative distinction from the research interests of the university and industrial sectors. Within this role the Laboratory has developed several areas of scientific and technical excellence and long-term commitment: inertial fusion, magnetic fusion, biomedical and environmental research, isotope separation, applied energy technology and other related research activities. Within these programs, LLNL interacts with both universities and private industry through faculty/student training and consulting and technology activities.

Los Alamos National Laboratory

James M. Williams
General University Activities Contact
Telephone Number (505) 667-3839

The Los Alamos National Laboratory (LANL) is operated for DOE by the University of California under the administrative management of the Albuquerque Operations Office.

The Laboratory's primary mission is the application of science and technology to problems of national security, that is, to the maintenance of a strong defense, the fulfillment of arms control commitments, and the guarantee of a secure energy supply for the future. In carrying out this mission, the laboratory serves as a liaison between research in academia and industry and complements the activities of both. Major programs include developing nuclear warheads, designing and testing advanced technology concepts, and maintaining an innovative weapons design program. In nuclear fission, programs include separating isotopes of uranium by laser induction, testing advanced reactor fuel elements, modeling reactor accident results for the Nuclear Regulatory Commission, evaluating biomedical consequences of nuclear energy production, and developing effective nuclear waste disposal methods. In nuclear fusion, programs include magnetically confined plasma devices (especially high-beta devices), laser-induced fusion, and safe handling techniques for large quantities of tritium. Other programs include nonnuclear energy, basic energy science, and technology utilization.

The Clinton P. Anderson Meson Physics Facility (LAMPF) is located at the Los Alamos National Laboratory and houses an accelerator which is a high current, 800 million electron volt (MeV), proton linear accelerator about one-half mile in length.

LAMPF is considered to be the world's most sophisticated nuclear science facility. It provides unique accelerator-generated beams of protons, pions, muons, neutrons and neutrinos for research programs in basic and applied nuclear science, particle physics, materials science, biomedical investigations, isotope production, and weapons technology.

This is a collaborative research center used by laboratory, university and industry researchers.

Oak Ridge National Laboratory
Post Office Box X
Oak Ridge, Tennessee 37831

Herman Postma

The Oak Ridge National Laboratory (ORNL) is operated for the Department of Energy (DOE) by Martin-Marrietta Energy Systems, Inc., under the administrative management of the Oak Ridge Operations Office.

The Oak Ridge National Laboratory primarily supports fission nuclear fuel cycle and magnetic fusion energy development through scientific research and technology; identifies and solves generic research problems in energy technologies such as materials, separation techniques, chemical processes and biotechnology; and is the major national source of production of stable and radioactive isotopes. Energy technology development at ORNL includes important efforts in residential and commercial energy conservation, renewable energy sources, and coal conversion and utilization.

ORNL has a close working relationship with the Oak Ridge Associated Universities (ORAU) and is a primary recipient of appointments under the ORAU University/Laboratory Cooperative Program. ORNL has a special arrangement with several small college consortia for honors-level, undergraduate student research appointments.

ORNL interacts widely with the academic community through User Facilities. Major facilities and equipment are made available to outside researchers to carry out cooperative and independent projects. Among these are the Holifield Heavy Ion Facility, which houses the accelerators and instruments that are dedicated to heavy-ion studies; the National Environmental Research Park; and many other accelerators, reactors, metallurgical and solid state physics, and biological facilities. In this manner, the Laboratory provides universities with ready access to state-of-the-art research capabilities, training facilities for faculty and students, and an opportunity for collaborative research in areas where these resources are not available to universities.

Director
Telephone Number (509) 375-2201

Sam Farmer
General University Activities Contact
Telephone Number (509) 375-2559

The Pacific Northwest Laboratory (PNL) is operated for DOE by Battelle Memorial Institute under the administrative management of the Richland Operations Office.

The mission of the PNL is the advancement and use of multidisciplinary scientific and engineering technology for national security and the nation's energy needs. In accomplishing this mission, high priority is given to safe and reliable nuclear energy, and to promising new concepts and technologies for operations at the Hanford site. Areas of disciplinary strengths and concentration include nuclear waste process development, nuclear fuel development and evaluation, spent fuel storage and reprocessing, inhalation toxicology, bioelectromagnetics, biology, ecology, atmospheric sciences, corrosion

chemistry, biomass research, nondestructive testing and evaluation, materials characterization and research, chemical engineering, health physics technology, and energy economics and policy analyses.

The laboratory provides a core capability for effectively utilizing the strengths of the universities and the private sector and has traditionally developed and maintained strong ties with the academic community. That resource is utilized through cooperative exploratory research efforts to accelerate application of new ideas, scientific research support to PNL efforts on team assignments, and exchange of staff and student research.

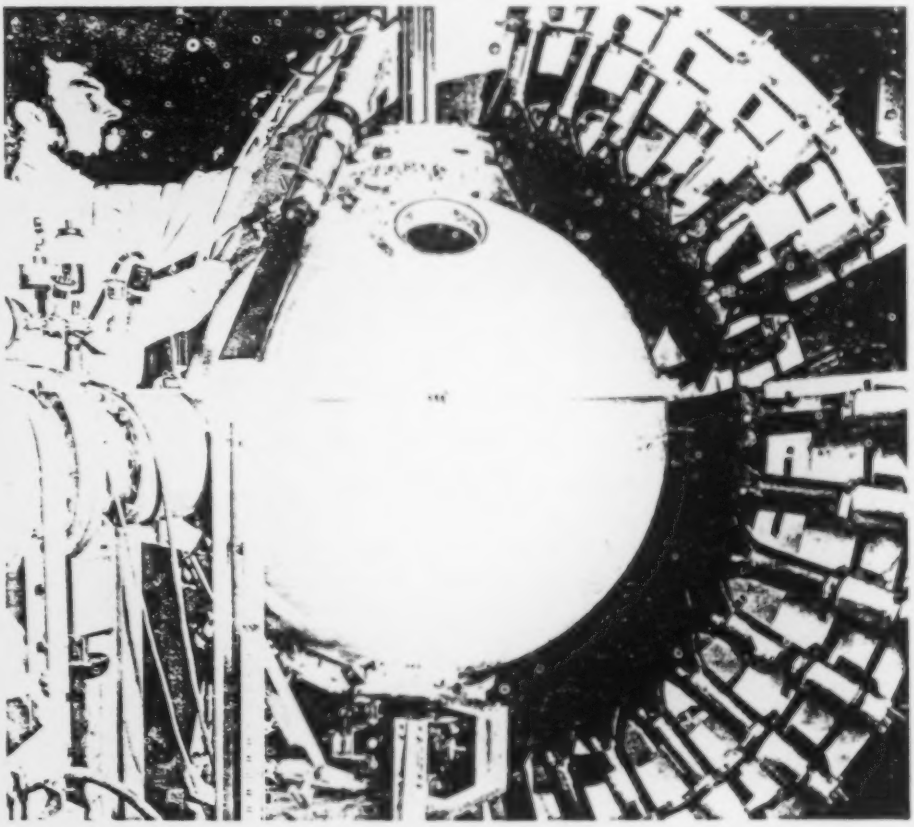
Sandia National Laboratories
P.O. Box 5800
Albuquerque, New Mexico 87185

George C. Dacey
Director
Telephone Number (505) 844-7261

James E. Schirber
General University Activities Contact
Telephone Number (505) 844-8134

The Sandia National Laboratories are operated for DOE by the Western Electric Company under the administrative management of the Albuquerque Operations Office.

The laboratories' principal mission has been and remains research, development, and engineering of nuclear weapons systems. Sandia is also responsible for energy programs in fossil, solar, fission, and basic energy sciences. Fundamental understanding and technological development are melded to create an environment conducive to generating new products and processes that are unlikely to be produced in either university or industrial laboratories. These new technologies are transmitted to the private sector through journals, workshops and other information-transfer mechanisms. Sandia Laboratories, Livermore, California, site includes the Combustion Research Facility, a major user-oriented center for fundamental research on combustion phenomena.



DOE Energy Technology Centers

Morgantown Energy Technology Center (METC)
P.O. Box 880
Morgantown, West Virginia 26505

Augustine A. Pitrolo
Director
Telephone Number (304) 599-4511

The Morgantown Energy Technology Center (METC) has responsibility for Unconventional Gas Recovery, Fluidized-Bed Combustion, Gas Stream Cleanup, Fuel Cells, Heat Engines, Surface Coal Gasification, and Component Development for Coal Conversion and Utilization Processes. These activities include the technology development for slurried fixed bed gasifiers, and fluidized-bed combustors as well as characterization, resource inventory, and field tests of unconventional natural gas reservoirs. METC is also responsible for Project Offices at Grand Forks, North Dakota, and Laramie, Wyoming.

In Control Technology, activities include the development of technologies for gas stream cleanup and for waste management and utilization. The primary objective of the gas stream cleanup project is to develop the required technology base for applications in post combustion/utilization devices used as advanced power conversion systems such as fuel cell and gas turbine combined cycles, and, in other conversion processes where significant process improvement results. The purpose of program activities in the fluidized-bed combustion area is to increase the utilization of coal by developing technologies for the pressurized fluidized-bed (PFB) process. The program is designed to provide the technology base necessary to evaluate the potential of both the air and steam combined cycle concepts. METC manages the activities in the Fuel Cells program, developing high-risk, high-payoff technology for cell and stack components. In the Heat Engines program, METC is conducting research and technology development directed toward the solution of major engineering design, durability and performance problems. In the Surface Coal Gasification program, METC is managing in-house and contract research and development involving advances in the state-of-the-art of coal gasification through new concepts development, generation of a technology data base for use by the private sector, and development of technologies for the refinement of existing gasification systems. METC's mission in Unconventional Gas Recovery involves the development of technologies for the recovery of gas from unconventional sources such as eastern Devonian oil shales, western gas sands, methane from coalbeds, methane hydrates and abiogenic gas.

Pittsburgh Energy Technology Center (PETC)
P.O. Box 10940
Pittsburgh, Pennsylvania 15236

Sun W. Chun
Director
Telephone Number (412) 675-6122

Fred W. Steffgen
General University Activities Contact
Telephone Number (412) 675-6133

The Pittsburgh Energy Technology Center (PETC) has responsibilities in the program areas of Direct Utilization, Coal Liquefaction, Coal Preparation, Coal-Water Mixtures, and Flue Gas Cleanup. This includes numerous research and development activities for the industrial use of coal and its derived synthetic fuels in an environmentally sound manner. PETC is also responsible for the handling of *all* unsolicited research proposals pertaining to any part of the Fossil Energy Program.

The PETC program objective in the area of advanced research on direct coal utilization is to establish the technology base and to develop the advanced fossil fuel combustion systems to accelerate the direct utilization of coal in industry and commercial power generation.

The goal of the Coal Liquefaction program is to establish a data base that will facilitate the private sector's development of coal conversion processes for economical production of environmentally acceptable synthetic liquid fuels through generic R&D in high-risk, long-term concepts that have potential for high payoff. The overall strategy will be to support a number of liquefaction concepts in parallel at the laboratory scale. Specific areas of concentration include: (1) the development of new and improved indirect liquefaction technology; (2) the development of more advanced direct coal liquefaction processes for further private sector development and demonstration; and, (3) the generation of supporting data in the areas of environmental and health effects, key instrumentation and components, engineering analyses and data base management.

The effort in the University Coal Research program is aimed at establishing research grants at colleges and universities for basic and applied research to improve scientific and technical understanding of the fundamental processes involved in the conversion and utilization of coal.

The Coal Preparation program focuses on the development of advanced coal cleaning technologies required by private industry to meet the anticipated growth in the demand for higher quality coal. Parallel efforts under Alternative Fuel Mixtures within the Combustion Systems activity are directed towards the preparation and utilization of highly cleaned coal water slurries as retrofit fuels for oil and gas designed units.

The flue gas cleanup program focuses on the development of a technology base for simple, cost effective and environmentally superior processes that remove pollutants from coal combustion gas streams in both utility and industrial boilers in light of existing, as well as anticipated, more stringent environmental standards.

DOE Sponsored Consortia

Associated Western Universities
142 East 200 South, Suite 200
Salt Lake City, Utah 84111

Donald Walker
Director
Telephone Number (801) 364-5656

Madeleine Franco
General University Activities Contact
Telephone Number (801) 364-5656

The Associated Western Universities is an outgrowth of the Associated Rocky Mountain Universities (ARMU) organized in Colorado in 1959 by several of the major universities in the Rocky Mountain Region. In 1964, the organization entered into a contract with the U.S. Atomic Energy Commission (AEC) to assist with the training of students and faculty members in the sciences and engineering associated with the nuclear industry through working with the AEC's contractor laboratories in the western United States. This relationship has continued with the Department of Energy. AWU does not carry out research but does encourage new research ideas among faculty of the universities by acting as a clearinghouse for ideas and by stimulating cooperation among the faculty and students of the universities and scientists at DOE and other laboratories.

As one participant in the DOE University-Laboratory Cooperative Program (administered by the Office of Energy Research Division of University and Industry Programs) AWU supports faculty and student participation in energy-related research projects at AWU cooperative laboratories and facilities throughout the Western United States. These facilities include such laboratories as the Los Alamos National Laboratory, Lawrence Livermore National Laboratory, Lawrence Berkeley Laboratory, Laboratory for Energy-Related Health Research, Laboratory of Biomedical and Environmental Sciences, Inhalation Toxicology Research Institute, Jet Propulsion Laboratory, Sandia National Laboratories and many, others. AWU coordinates activities for the Lab/Coop program including: undergraduate research study; graduate thesis and non-thesis research; and faculty and/or post-graduate research appointments.

AWU has cooperative arrangements with twenty-six major facilities in the western United States. Research disciplines include the physical sciences—biology, chemistry, geology, mathematics and computer science, and physics—and several of the engineering fields such as chemical, electrical, mechanical, metallurgical, nuclear and petroleum engineering. Application forms for AWU programs may be obtained from the address indicated above.

Northwest College and University Association for Science
Joint Center for Graduate Study
100 Sprout Road
Richland, Washington 99352

Bryan Valett
Director
Telephone Number (509) 375-3176

The Northwest College and University Association for Science (NORCUS) is an association of fifty-two schools in the five northwest states: Alaska, Idaho, Montana, Oregon and Washington. Members include institutions at all levels—from four-year graduate universities to two-year community colleges. Located at the Joint Center for Graduate Studies, NORCUS conducts appointment programs in science and engineering. The Association is supported through grants with the University of Washington acting as the administrative contractor and interfaces with the six DOE contractor laboratories in the Richland area.

NORCUS programs include: undergraduate research participation; graduate student research; and faculty research appointments. Faculty and student appointments may be made in the following fields: chemistry, mathematics, metallurgy, physics, computer science, engineering (nuclear, mathematical, chemical, electrical), biology, radiobiology, environmental science, and alternative energy studies.

Application forms for NORCUS programs may be obtained from the address indicated above.

Oak Ridge Associated Univerities
Post Office Box 117
Oak Ridge, Tennessee 37830

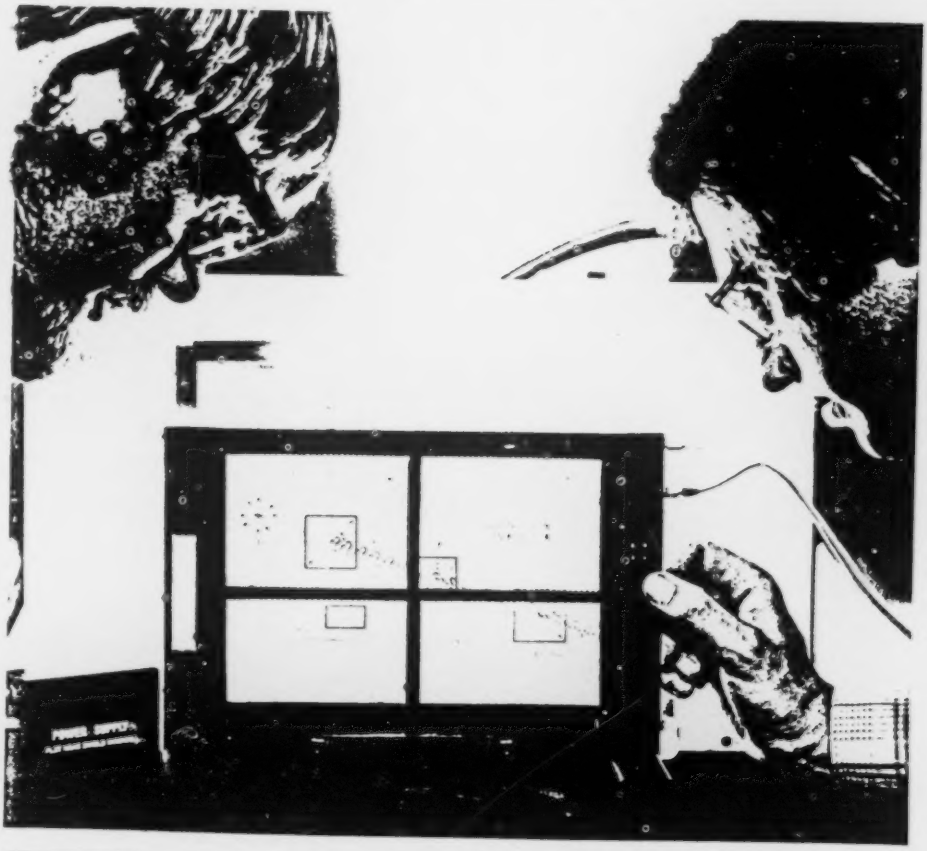
William E. Felling
Executive Director
Telephone Number (615) 576-3300

Al Wohlpart
General University Activities Contact
Telephone Number (615) 576-3421

The Oak Ridge Associated Universities (ORAU) is a private, not-for-profit association of more than 50 colleges and universities mainly in the southeastern U.S. It has been a contractor of the U.S. Department of Energy (and its predecessor agencies) for over 35 years conducting research and educational programs in the areas of energy, health and the environment.

Within the University Laboratory Cooperative Program research opportunities are provided for faculty, graduate students and undergraduate students in both summer and academic year programs at seven DOE facilities (including the Oak Ridge Associated Universities; the Oak Ridge National Laboratory; Savannah River Laboratory; the Savannah River Ecology Laboratory, Center for Energy and Environment Research, Puerto Rico; Atmospheric Turbulence and Diffusion; and the Martin Marrietta Energy Systems, Inc.). These research programs relate to energy production, utilization, conservation and their societal implications. Appointments are available in the life, physical and social sciences, mathematics; and engineering.

Application forms for ORAU programs may be obtained from the address indicated above.



Part IV.
DOE Procurement and Assistance Policies/Procedures

Introduction

The Assistant Secretary for Management and Administration is the business manager of DOE responsible for budget, financial operations procurement, cost estimating and the development of business-related policy.

Of the offices reporting to the Assistant Secretary, the Director of Procurement and Assistance Management, is the principal official and business advisor on all procurement, financial assistance, sales and other business arrangements for DOE. The Director is responsible for establishing overall policy and regulations for the Department in the areas of procurement, financial assistance, sales, and contract management; providing functional management and review of the field buying offices; providing support for advance planning related to procurement and financial assistance programs; and managing the operation of the Source Evaluation Board process. The Director is also responsible for the Headquarters Office of Procurement Operations, which is the largest procurement office in DOE.

Some of the responsibilities and activities of the Procurement and Assistance Management Directorate are discussed on the following pages.

There are two principal means by which a researcher may obtain DOE funding or other support for research projects. Each of these begins with the preparation and submission of a proposal. A proposal submitted in response to a solicitation issued by DOE is termed a "solicited proposal," whereas a proposal prepared and submitted solely on the researcher's own initiative is an "unsolicited proposal."

Information detailing the steps for preparing and submitting a solicited proposal will be found within the text of the solicitation. For unsolicited proposals, researchers who have original, unsolicited ideas that they believe would be of interest to one of the program entities identified in Part I, will find an overview of the steps necessary to obtain DOE support in Part IV.

Sections of Part IV describe generally the DOE solicitation process including solicitation characteristics, proposal requirements, proposal evaluation, types of award instruments, and DOE project management procedures.

It should be noted that the Federal Procurement Regulations (FPR's)* and the DOE Procurement Regulations (DOE/PR's)* generally govern all procurement relationships with DOE, and the DOE Financial Assistance Rules (issued October 5, 1982) govern all financial assistance relationships with the Department. DOE regulations for procurement are found in 41 Code of Federal Regulations (CFR) Chapter 9; for grants and cooperative agreements, they are found in 10 CFR part 600.

Competitive Solicitations

There are several types of competitive solicitation documents issued by DOE. Various types of solicitations that call for the submission of proposals or applications are described below.

- *Program Opportunity Notice (PON)*—A notice used principally to solicit competitive proposals for non-nuclear energy demonstration projects when there is a stated general objective, but no prescribed statement of work, and diverse approaches are desired. PON's may result in the award of procurement contracts or financial assistance instruments.
- *Program Research and Development Announcement (PRDA)*—An announcement used to solicit a broad mix of research, development, and related energy project proposals. While a Program Opportunity Notice is geared strictly to demonstration projects utilizing existing, commercially applicable technology, a PRDA solicits proposals for projects in areas where research and development is required within broadly defined areas of interest, but it is difficult to describe in detail the nature of the work contemplated because of:
  - — The multiplicity of possible approaches available for solving the problems;
  - — The desirability of using several organizations in solving the problems posed;
  - — The expectation that many proposers will have qualifications or specialized capabilities that will enable them to perform portions of the program, so that the support may be broken into segments that cannot be ascertained in advance; and
  - — The desirability of fostering new and creative solutions.

  PRDA's may result in the award of procurement contracts or financial assistance instruments.
- *Solicitation for Financial Assistance Applications*—A program rule or regulation or other publicly available document used to invite the submission of applications for grants and/or cooperative agreements by a common due date or within a prescribed period of time. The solicitation or a notice of the availability of the solicitation will be published in the *Federal Register* and, as appropriate, in the *Commerce Business Daily*.

Synopses of these competitive solicitation notices are published in the *Commerce Business Daily* and may also

*Effective April 1984, the Federal Procurement Regulations (FPR's) and the DOE Procurement Regulations (DOE/PR's) were replaced by the Federal Acquisition Regulation (FAR) and the Department of Energy Acquisition Regulation (DEAR).

be published in professional journals and news publications. Such publication is in keeping with the DOE policy of providing timely notice to the public as to the availability of assistance awards and acquisition contracts.

Two other types of solicitation documents are used to solicit competitive proposals for procurement contracts in accordance with the Federal Procurement Regulations:

- *Invitation for Bids (IFB)*—A document used to solicit bids in response to detailed specifications. Award is based on price competition, and a fixed price type of procurement contract usually results. Requirements are usually of a hardware nature and formal advertising procedures are followed. They contain detailed specifications, terms and conditions of the procurement. Each invitation for bid also sets forth the place, date and time for the formal opening and recording of bids. The evaluation and award process is conducted in strict compliance with the Invitation for Bids and in accordance with procurement regulations.
- *Request for Proposal (RFP)*—A document used to solicit proposals in response to a broader statement of work that normally incorporates performance specifications rather than detailed design specifications. Each Request for Proposal sets forth the place, date and time for the submission of proposals. The evaluation, selection, negotiation and award process is conducted in accordance with the terms of the solicitation document and procurement regulations.

Universities responding to competitive announcements will be expected to comply with all conditions stated in the announcements for proposal submission, review and evaluation. If an award results, they will similarly be expected to meet all stipulated requirements for reporting, audits and the like.

Unsolicited Proposals

Policies

Because present and future energy needs demand full exploitation of all energy alternatives, it is DOE policy to encourage individuals and organizations to submit unsolicited proposals on unique, innovative approaches and ideas that they believe merit public support.

In furtherance of this policy, DOE will:

- Publicize DOE interest in unsolved technical issues whose solutions are considered relevant to the accomplishment of DOE's mission;
- Process unsolicited proposals in an expeditious manner and keep proposers advised as evaluation and acceptance decisions are made;
- Ensure that all possible sponsors within the Department are aware of the proposal's existence;
- Ensure that each proposal is evaluated in a fair and objective manner;
- Ensure that each proposal is used only for its intended purpose (all Government and Non-Government personnel handling unsolicited proposals shall exercise extreme care to ensure that the information contained therein is not duplicated, used or disclosed in whole or in part for any purpose other than to evaluate the proposal, without written permission of the offeror);
- Encourage the submitter of an unsolicited proposal to mark it "Proprietary Data" with a legend restricting the disclosure and use of the data as marked in the proposal. If a proposal contains proprietary data, it may be marked with notice in accordance with the procedure in the DOE-PR, 9-3.150-2(a) or 10 CFR 600.18. (The disclosure of such information concerning trade secrets, processes, operations, style of work, apparatus, and other matters, except as authorized by law, may result in criminal penalties);
- Encourage program staffs to develop and publish statements of program interest in those technical areas and new technology directions that might be addressed by unsolicited proposals from the research community; and
- Obtain signed non-disclosure statements from reviewers outside of the Government when external review is deemed necessary and appropriate. (The non-disclosure statement ensures that the reviewer will use the information contained in the proposal for evaluation purposes only.)

Procedures

An unsolicited proposal is submitted solely on the initiative of the proposer. The idea presented in a proposal may be prompted by a Notice of Program Interest; however, this is not a prerequisite for the submission of an unsolicited proposal. A Notice of Program Interest may be published by DOE whenever the Department wishes to stimulate a particular program effort but has not specifically identified any projects. Notices provide information about DOE interest in innovative approaches applicable to specific problem areas involving energy and related technology utilization. They are *not* formal solicitations, but are instead a communication device that informs and helps potential proposers focus on areas where unsolicited proposals may be mutually beneficial to DOE programs and the proposer. They are generally published

in the *Commerce Business Daily* or the *Federal Register*, and widely distributed to industry associations, including small business associations; schools, colleges and universities; appropriate professional and scientific journals; state, local and regional governmental organizations; other DOE offices; and individuals and organizations who request copies on a one-time basis.

In the unsolicited proposal, the proposer must present project objectives and their pertinence to the DOE mission; justify the rationale of the approach and the methods to be employed; indicate the relevant qualifications of the investigator(s) and sponsoring institution, and the level of funding required to attain the objectives. The proposal should be self-explanatory and written with clarity and thoroughness. It alone will serve as the means to persuade the staff of DOE, and other qualified members of the scientific and engineering community who might review it for DOE, that the proposed project is worthwhile.

The Department of Energy is not responsible for costs incurred in the preparation of either solicited or unsolicited proposals. Prior to expending resources in the development of an unsolicited proposal, prospective proposers are encouraged to consult informally with DOE program personnel by letter, telephone, or personal visit to ascertain their potential interest. Such preliminary contact serves to establish an understanding between the proposer and DOE, and should reduce paperwork and loss of time. Note that these informal discussions do not constitute authorization to perform work at Government expense in anticipation of an award. The names of DOE staff members consulted should be included in the transmittal letter that accompanies the unsolicited proposal, to ensure their receipt of the proposal.

The unsolicited proposal forms the basis for both further technical evaluation and contract negotiations. Although no particular format need be followed for the submission of unsolicited proposals, there are several items that must be included. These are basic information about the submitter, his or her organization and proposed project dates; project business and financial information including cost and labor hour requirements; and project technical information including a detailed statement of work with sufficient technical detail to permit a meaningful evaluation, and facility and equipment requirements, if any.

General policy and procedures concerning the receipt, evaluation and acceptance of unsolicited proposals are set forth in Federal Procurement Regulations 1-4.9, DOE Procurement Regulations 9-4.9 and DOE Assistance Regulation 600.14. It should be noted that the Department encourages the submission of multiyear proposals where the research can be reasonably expected to continue over several years.

Further information on the submission of unsolicited proposals can be found in the DOE booklet entitled "Guide for the Submission of Unsolicited Proposals" (DOE/MA-0095). The material in the booklet, along with information learned through informal consultation, will assist the proposer in producing an unsolicited proposal that contains sufficient information to permit evaluation. This booklet is available from the office listed below.

There are no specific dates for the submission of unsolicited proposals; but, because a comprehensive review is required before a proposal can be acted upon, new proposals should be submitted as early as possible, usually a minimum of six months in advance of the desired period of support. However, it should not be assumed that in all cases a six-month lead time is adequate. Proposals should be submitted to:

Unsolicited Proposal Coordinator
Reports and Analysis Branch
Procurement and Assistance Management Directorate
U.S. Department of Energy
Washington, D.C. 20585

The Unsolicited Proposal Coordinator is responsible for logging and monitoring the status of all unsolicited proposals formally submitted to DOE. If the proposer has identified the appropriate program office to which a specific proposal is to be reviewed, the unsolicited proposal may be sent to that office with a letter of transmittal. That office is then responsible for advising the Unsolicited Proposal Coordinator of its receipt for control purposes. The Coordinator will acknowledge receipt of the unsolicited proposal, provide the DOE control number and identify the program office(s) to which the proposal has been referred. Some proposals may have the potential for support by more than one DOE program office, in which case the proposal may be referred to all potentially interested groups.

It should be noted that the Office of Minority Economic Impact, pursuant to Section 211(e)(1) of Public Law 95-619 and 10 CFR Part 800, has authority to issue loans to minority business enterprises to assist them by financing up to 75 percent of the costs incurred in preparing bids or proposals seeking DOE contracts or assistance. Information regarding loan availability, eligibility criteria, and application procedures may be obtained from:

San Francisco Operations Office, USDOE
1333 Broadway
Oakland, California 94612
Attn: Grants and Loan Division
Phone: (415) 273-4461

Proposal Review and Evaluation

Solicited Proposals

Solicitations set forth the specific criteria to be used in the proposal evaluation and review process. Such proposals are normally reviewed only by Government personnel.

Unsolicited Proposals

A. Review

Prior to making a comprehensive evaluation, DOE will review the proposal to determine whether the document contains the minimum prescribed information, has been approved by a person authorized to represent the proposer organization and falls within the scope of an unsolicited proposal. If the proposal satisfies the requirements of the preliminary review, copies will be forwarded to appropriate offices for evaluation.

If the document does not satisfy all of the foregoing requirements, it will be treated as a preliminary proposal. If the decision made as a result of this preliminary review is unfavorable, no further comprehensive evaluation may

be made. The proposer will be told how the document has been interpreted and the reason it is not being considered as an unsolicited proposal. However, if the document contains most of the information required and appears to have technical merit, the missing information may be requested so that it can be processed as an unsolicited proposal.

B. Evaluation

The detailed evaluation criteria used in reviewing an unsolicited proposal are contingent upon whether the project, for which the proposal is to be considered, is principally one of acquisition or assistance.

- If the project is principally one of assistance, the supporting instrument will be an assistance instrument, i.e., either a grant or cooperative agreement. The evaluation criteria for assistance instruments are set forth in the DOE Assistance Regulations. (See 10 CFR part 600)
- If the project is principally one of acquisition, the supporting instrument will be a contract. The evaluation criteria for contracts are set forth in the Federal and DOE Procurement Regulations. (See FPR 1-4.9 or DOE/PR 9-4.9)

For the past three years, approximately 22 percent of the unsolicited proposals reviewed by DOE were funded. If DOE decides to support a proposal, the proposer will be so advised but may be asked to submit additional details, to revise budgets, or to confirm the proposal goals as approved. Plans for initiating the project may be agreed upon at that time. However, no actual commitment of funds may be made by the recipient until formal notification action is completed. Preaward costs are generally not allowable. When the program office has determined that a proposal will be funded, contract office personnel will be requested to negotiate the award instrument with the firm concerned. Cognizant DOE offices have been designated for most major colleges and universities.

An unsolicited proposal may propose activities that are also of interest to other Federal agencies. In such cases, with the prior written approval of the proposer, interagency proposal evaluation may be initiated. If the proposal is found acceptable, another agency may fund the unsolicited proposal or DOE may jointly fund the program with the other agency.

Types of Award Instruments

Projects usually fall into one of two classes, acquisition or assistance. The determination of whether a project is one of acquisition or assistance is made at a DOE program policy level.

There are three types of instruments generally used by DOE to provide funds for research projects: grants, cooperative agreements, and procurement for contracts (including Special Research Contracts). The choice of award instrument lies within the administrative discretion of DOE, except when prohibited or limited by law. The decision as to which form of award instrument will be used is based on the purpose of the project and the extent of Federal involvement necessary to ensure project success. An award instrument identifies the terms and conditions, and the nature of this relationship between DOE and the recipient.

- A procurement contract is used as the funding instrument whenever the principal purpose is the acquisition by purchase, lease, or barter of property or services for the direct benefit or use of the Federal Government, or whenever DOE determines in a specific instance that the use of a contract is appropriate.
  - —A Special Research Contract (SRC) is a simplified form of procurement contract which may be used for educational and not-for-profit research institutions conducting basic research, where the annual DOE support does not exceed $1,000,000.
- An assistance instrument is used to provide support whenever the principal purpose is to accomplish a public purpose of support or stimulation authorized by Federal statute.
  - —A "grant" is used whenever no substantial involvement is anticipated between DOE and the recipient during performance of the activity.
  - —A "cooperative agreement" is used whenever substantial involvement is anticipated between DOE and the recipient during performance of the activity. Each cooperative agreement shall include an explicit statement of the nature, character and extent of the anticipated DOE involvement.

Patent, Data and Copyrights

Under DOE statutory patent policy, DOE normally reserves the right to title in all inventions conceived or first actually reduced to practice in the course of or under contracts, grants, or other agreements involving research, development or demonstration. In such instances, the contractor or assistance recipient is normally reserved a royalty-free, nonexclusive, revocable license for the use of such inventions. However, at or before award, a contractor or recipient is permitted to request an advance waiver of the Government's rights in inventions. Also, the contractor or recipient may request waiver of the Government's rights in identified inventions after the time of contracting.

The recent passage of Public Law 96-517 now permits small business firms, universities and other educational institutions and non-profit organizations to retain title to inventions if they elect to do so. Only under exceptional circumstances will the Government retain title to an invention discovered or reduced to practice under a funding arrangement with these types of organizations. The Government is provided with a royalty free license, however.

DOE recognizes that a contractor, assistance recipient or their employees may desire to publish, within the limits of security requirements, information regarding scientific or technical developments made or conceived in the course of their work under agreement with DOE. So that premature public disclosure of such information will not adversely affect the patent interest of DOE, the contractor, or the assistance recipient, the contract or grant provides DOE with a 60-day period to determine whether patent protection should be obtained prior to release of information.

DOE Procurement Regulations, and DOE Assistance Regulations contain policies and detailed procedures on patents, data and copyrights.

Classification Research and Security Considerations

Classification

Most proposals for DOE research and development projects are unclassified. If, however, during the evaluation of a proposal it is found that the work will be in or border on a classified topic, any resulting contractual arrangement will take this into account and the assistance recipient or contractor will be required to comply with applicable Government security regulations. Certain contractual provisions or assistance conditions can be included in an award instrument to allow for termination of the arrangement, should a classified topic develop during the course of work.

Security

Where possible, an unclassified proposal should be submitted. However, if this is not feasible, the proposal must be classified in accordance with its content. Additional guidance with regard to the preparation, handling and disposition of a classified proposal may be obtained from:

Director of Security
U.S. Department of Energy
Washington, D.C. 20585

Reports

Recipients of financial assistance or procurement contract awards will be expected to satisfy reporting requirements stipulated in the solicitation, the award instrument, or applicable regulations. For additional information on procurement contract reporting, see the applicable DOE Orders.*

The selection of appropriate reports, their frequency and the amount of detail will vary with several factors including the program objectives, amount of funding and type of instrument awarded. DOE program managers have been instructed to use discretion in report selection in order to keep administrative burdens to a minimum.

Audits

Office of Management and Budget Directives require contracts, grants and cooperative agreements to include a requirement to examine periodically the books and records of the recipients of a contract or financial assistance award.

Audit functions of the Department are the responsibility of the DOE Inspector General and are performed in accordance with generally accepted auditing standards and applicable Federal regulations. However, the cognizant audit agency for most colleges and universities is the U.S. Department of Health and Human Services. In certain instances, DOE itself may conduct an audit of awards to a university. Audits of commercial organizations are generally conducted by the Defense Contract Audit Agency (DCAA).

The objectives of audits are to determine whether a contractor's or assistance recipient's management, accounting, procurement, and property control systems and procedures provide assurance to DOE that costs claimed are reasonable, allowable and allocable under the procurement and assistance terms and conditions; and to review for compliance with applicable Federal and DOE procurement and assistance regulations, and provide recommendations for improvement where needed.

Audit questions should be directed to the Office of Policy, Business and Financial Policy Branch, Procurement and Assistance Management or the Office of the Inspector General, U.S. Department of Energy, Washington, D.C. 20585.

Glossary

B/O (Budget Outlays) — The sum of the outlays (disbursements from appropriations and funds, less offsetting receipts.

Cooperative Agreements and Grants — Award instruments between the DOE and state government, university, or other recipient whereby the DOE provides assistance in the form of money, property, services or anything of value to the recipient to accomplish a public purpose of support or stimulation. A cooperative agreement is similar to a grant except that it describes a relationship whereby the Government has substantial involvement with the recipient during the performance of the effort. A grant calls for comparatively little Government involvement.

Financial Assistance — Government-provided funds or aid in kind to accomplish a public purpose of stimulation or support authorized by Federal statute. It includes cooperative agreements and grants.

Notice of Program Interest — A published statement of DOE program interest in general technical problem areas needing investigation which might be addressed by unsolicited proposals.

Procurement Contract — A contractual instrument used when the Federal Government procures property or services for its direct benefit, i.e., use or consumption.

Program — An organizational set of activities directed toward a common purpose, objective, or goal undertaken or proposed by an agency in order to carry out responsibilities assigned to it.

Project — An endeavor with a specific objective to be met within prescribed time and dollar limitations and which has been assigned for work definition or execution.

Solicited Proposal or Application — A written response to a formal solicitation notice issued by the Government, generally in a competitive acquisition or assistance process.

Unsolicited Proposal — A written offer to perform a proposed effort submitted solely on the initiative of the offerer, with the objective of obtaining financial support and not in response to a specific request of the Government.

An Assessment of the Relationships Between The Department of Energy and Universities and Colleges

Volume I

Prepared by
The University Programs Panel
August 1983

A Report of the
Energy Research Advisory Board
to the
United States Department of Energy
Washington, D.C. 20585

Energy Research Advisory Board

(202) 252-8933

Honorable Donald Paul Hodel
Secretary of Energy
Washington, D.C. 20585

Dear Mr. Secretary:

I am pleased to forward the final Report prepared by the University Programs Panel of the Energy Research Advisory Board (ERAB). This report, discussed and approved unanimously by the ERAB on August 4, 1983, was prepared in response to the request by former Deputy Secretary W. Kenneth Davis on November 5, 1982, to examine the interrelationships between the Department of Energy and the Nation's colleges and universities. The Board was also requested to evaluate the effectiveness of the Department's policies and programs with the academic community.

The Department and its predecessor agencies have had long-standing relationships and programs with universities, both directly in terms of on-campus research projects and indirectly through the programs and resources of the National Laboratories. The University Programs Panel looked in depth at university participation in Departmental programs. There is no question that the Department has had a major and positive impact on many areas of university research and education, particularly in the nuclear and physical sciences. However, the Panel also noted a number of issues and concerns that have developed over time and have unduly affected and limited the participation of university researchers in Departmental programs. These issues are dealt with at length in the Panel's report and a number of recommendations are proposed to reduce or eliminate the reasons behind them.

Among the principal findings and recommendations in this report is the need for the Department, at the level of the Secretary, to articulate clearly its view of the proper university role in support of Departmental programs. Related to this is the need for the Department to establish an agency-wide R&D program planning process which provides opportunities for university and other scientists to contribute to the development of future research agendas and priorities for each major Departmental program. The Panel recommends that the Department should explicitly recognize its obligation to play a significant supporting role in the overall national effort to ensure adequate numbers of highly skilled scientists and engineers. Finally, the Panel recommends that the exchange of information between university scientists and administrators and Departmental program and policy staff needs to be significantly improved and expanded.

The Board agrees that the Nation's universities are an essential resource for the Department both in terms of the development of new scientific and technical concepts and in the preparation of the next generation of scientific and technical leadership for future energy R&D programs. The recommendations in this report are designed to suggest to the Department means by which university capabilities can be utilized even more effectively in support of the Department's missions.

Sincerely,

Louis H. Roddis, Jr.
Chairman, Energy Research
Advisory Board

Mr. Louis H. Roddis, Jr.
Chairman
Energy Research Advisory Board
U.S. Department of Energy
Washington, D.C. 20585

Dear Louis:

I am pleased to transmit on behalf of the University Programs Panel of the Energy Research Advisory Board its report prepared in response to a request dated November 5, 1982, from former Deputy Secretary W. Kenneth Davis asking the Board to examine the roles and missions in energy research and development undertaken by the universities and the effectiveness of the Department's policies toward and working relationships with the academic community.

The Panel very much appreciates the cooperation of the staff of the Department of Energy and the detailed, helpful information provided by the universities.

Sincerely,

Ivan

ABSTRACT

The Final Report of the University Programs Panel of the Energy Research Advisory Board responds to the Department of Energy's request to examine "the effectiveness of the Department's policies toward and working relationships with the academic community." In the course of this study, the Panel examined the entire spectrum of the Department's relationships with and programs for universities and university scientists and students. This included the direct support provided by Department programs for on-campus research and related manpower development and the indirect, but substantial, assistance provided through the Department's national laboratories to university faculty and students.

The Panel received numerous comments and suggestions from representatives of the academic community regarding their relationships with the Department. In addition, presentations were made to the Panel by senior Department program and policy staff, by representatives of the national laboratories, and by senior staff from other Federal agencies with substantial university programs. A series of in-depth case studies and assessments were also carried out on a number of past and current Departmental programs involving universities.

Based on this extensive information and related material, the Panel has identified seven major issues and concerns which require attention if the Department's relationships with the academic community are to be strengthened and improved. These issues are

- the lack of comprehensive and consistent Department-wide policies toward the involvement and support of universities in energy R&D and related programs,
- the Department's management and procurement policies and procedures related to the support and oversight of university programs,
- relationships between the Department's national laboratories and the academic community,
- participation of university scientists and students in the Department's various energy technology development programs,
- the Department's role in the development of professional-level manpower,
- communications between the Department and the academic community, and
- university involvement in multidisciplinary and interdisciplinary energy R&D.

Based on analyses of these issues, the Panel has considered and adopted a number of recommendations for the consideration of the Department designed to resolve or eliminate, wherever possible, the problems that have developed over time between the Department and the academic community. The principal recommendation of the Panel is that the Department, at the level of the Secretary, should clearly state its view of what the proper university role is in support of Departmental programs. Related to this recommendation is the need for the Department to establish an agency-wide R&D program planning process that would include opportunities for university and other scientists to contribute to the establishment of future "research agendas" and resulting priorities for each major program in the Department. Other recommendations are directed at improving the Department's policies and procedures for the award and administration of university research grants and contracts, increasing university involvement in technology-oriented R&D, and ensuring that research proposals submitted to the Department for consideration should be subjected to

comparable standards of external peer review whether the proposal is from a national laboratory or university-based group.

Finally, the Panel believes the Department's relationships with the academic community would be significantly improved if communications between Departmental staff and university officials were strengthened and expanded. Therefore, the Panel recommends that the Department consider establishing a "forum" of university presidents and other senior officials that would meet periodically with the Secretary and DOE senior staff to review mutual problems and concerns, with resulting appropriate follow-up by policy and program staff.

1. INTRODUCTION

This report was prepared in response to a request by the Deputy Secretary of Energy on November 5, 1982 (Attachment A), that the Energy Research Advisory Board (ERAB) examine the effectiveness of the Department's policy toward and working relationships with the nation's universities. The Deputy Secretary asked the Board to explore the following:

- Is the Department effectively utilizing the general capabilities of the university community in both fundamental and energy research?
- Is the Department effectively utilizing universities, vis-a-vis laboratory and private sector groups, in energy research and technology development programs?
- What responsibilities and mechanisms are appropriate for the Department in professional-level manpower development including, but not limited to, support for graduate students, postdoctoral researchers, and younger faculty members?
- What current factors, actual or perceived, foster or impede good working relationships between the Department and the academic community?
- In what ways, if any, could the Department improve the effectiveness of the working relationships between the DOE laboratories and the universities including, for example, the planning and conduct of joint research programs?
- What changes, if any, should the Department make in order to provide the most effective support of university-based energy research?

To perform the requested study, the Board established a Panel on University Programs, composed of both Board and non-Board members (list follows title page). The Panel was charged to report its findings to the full Board for review and approval prior to transmittal to the Secretary.

1.1 Methodology

1.1.1 Review

The Panel conducted a general review of the historical and existing relations between the Federal Government and the nation's universities, with particular emphasis on recent trends in support by various agencies for research and development (R&D), for collaborative programs with government laboratories and industry, and for the development of professional manpower. This material is summarized in Volume II, Chapter 4.

A specific summary of university programs supported by DOE and it predecessor agencies is included as Attachment B to Volume I.

1.1.2 Comments

Comments on DOE-university relationships were solicited by letter from

- presidents of selected universities and colleges,
- presidents of professional scientific and engineering societies,
- presidents of educational associations and consortia,
- deans of schools of engineering,
- individual university scientists and engineers with past or current working relationships with the Department, and
- directors of the Department's multiprogram national laboratories.

These requests and respondents are listed in Attachment C to Volume I, and the overall results are tabulated in Volume II, Chapter 2 and Appendix D.

1.1.3 Presentations

In addition, at several meetings, the Panel heard presentations on university programs from

- the Director of the Office of Science and Technology Policy;
- representatives of the Department of Defense (DoD), National Aeronautics and Space Administration (NASA), and the National Science Foundation (NSF);
- university presidents and research administrators;
- university scientists with support from DOE;
- DOE National Laboratories; and
- DOE senior program and policy staff.

See Attachment D for agendas of the several meetings of the Panel.

1.2 Additional Background

The Panel recognizes that energy is not a single technical, scientific or academic discipline. The areas of science and engineering important to different energy forms and sources and to conservation vary so widely that any attempt to address the Department's program as a generic issue is bound to fail. It is also important to recognize that the academic institutions capable of carrying out energy-related research vary widely in size and scope from large, graduate-oriented research universities to small, undergraduate colleges. Furthermore, a large amount of energy-relevant research is supported by other Federal agencies and by industry. This report does not assess these other efforts in detail but points out that DOE-university programs must be structured in a broad national context.

The Panel's study points up a variety of troublesome aspects of DOE's working relationships with the university community that, *unless dealt with decisively*, can erode a historic partnership that has been and is essential to the accomplishment of the Department's mission. But the overall picture is far from bleak. There have been important recent and continuing efforts in DOE to improve the relationships between the Department and the university community. Those include progress towards the improvement of DOE patent policies and procedures related to university research, the expanding use of multiyear awards for university research the initiation of a program to improve university research instrumentation, renewed emphasis on the use of facilities at the national laboratories by faculty and students for research and education, and significant steps in the initiation of research and related educational activities at some of the nation's Historically Black Colleges and Universities. In addition, the Department has had historically, and continues to have, a major impact on a number of university research and education areas, particularly in the nuclear and physical sciences and in nuclear medicine. For example, national preeminence in high-energy and nuclear physics is due in no small part to the unique and ongoing partnership among the Department of Energy, the DOE national laboratories, and the university community. The Department can take justifiable pride in its accomplishments in these fields.

1.3 Structure of the Report

Based upon a review of DOE's recent programs of support for university-based R&D and education (Attachment B); of information collected from universities, professional organizations, and the national laboratories (Attachment C); and of current information presented by the several program offices of the Department and representatives of the Office of Science and Technology Policy (OSTP), DoD, NASA, and NSF (Attachment D), seven major issues were identified as requiring attention if existing shortcomings in the Department's utilization of the nation's academic capabilities are to be corrected and the resulting improvements sustained. These are

1. the lack of comprehensive and consistent DOE-wide policies toward the involvement and support of universities in energy R&D and related programs,
2. DOE procurement policies and procedures related to the support of university programs,
3. the relationships between universities and the Department's national laboratories,
4. the participation of university scientists in DOE's energy technology development program,
5. the Department's role in the development of professional-level manpower,

6. communications between the Department and the academic community, and
7. university involvement in multidisciplinary and interdisciplinary programs.

These issues constitute the main headings of the report. Each is discussed, findings and conclusions are given, and recommendations for actions are suggested.

2. DOE POLICIES REGARDING UNIVERSITY SUPPORT

Issue: The Department lacks a consistent agency-wide policy for university involvement in energy R&D and related manpower development.

The Panel recommends that the Secretary of Energy issue a policy statement affirming the importance of university involvement in all appropriate Departmental programs and that the support of university-based research and manpower development by all Departmental programs and offices be conducted in conformity with this policy.

2.1 Introduction

2.1.1 Sources of support

Support for university-based research in the Department of Energy is provided from each of the major outlay program offices (Energy Research, Fossil Energy, Nuclear Energy, Conservation and Renewable Energy, Defense Programs, etc.). In FY 1983, 75% of DOE university research funding will be provided through the Office of Energy Research (ER). University support from other DOE programs, now minimal, has fluctuated significantly during the past few years because of changing national policies and priorities for the role of the Department in development of energy technologies. Table 2.1 summarizes direct university funding from each DOE program. In addition to this direct funding of university research by DOE programs, over $200 million of indirect support was provided to university faculty and students in FY 1982 through the Department's national laboratories (Table 2.2). This total includes an estimate of the portion of the operating costs of laboratory research facilities when they are "used" by university scientists (additional information on DOE university support may be found in both Attachment B and in Volume II).

2.1.2 Selection of performers

Each program office in the Department is responsible for carrying out its R&D programs using the most appropriate mix of performers, whether at national laboratories, at universities, or in industry, to meet particular program needs and requirements. Different approaches to this are followed by the various program offices. Some offices have assigned significant technical management responsibility for specific R&D programs to one or more of the DOE national laboratories. The laboratories in turn may contract with industrial and university researchers for elements of these assigned programs. This is the procedure, for example, in several of the reactor development programs of the Office of Nuclear Energy where national laboratories have lead mission assignments.

2.1.3 Procedures for proposals

A theoretical advantage of the present decentralized process is that there are a number of potential "homes" in the Department for the support of research in particular areas; for example, a scientist interested in pursuing materials research can contact more than one program office in the Department for review of a particular proposal, depending on the

Table 2.1. Department of Energy university R&D funding by major program office[a]

(budget outlay in millions of dollars)

Program	FY 1981 actual	University R&D funding (%)	FY 1982 estimate	University R&D funding (%)	FY 1983 estimate	University R&D funding (%)

[b]NA = data not available.

[c]Includes appropriate proportion of operating costs of user facilities at laboratories attributable to university research groups.

Source: DOE and laboratory staff.

nature and focus of the project. In fact, however, inconsistent procedures for soliciting and processing proposals by the various program offices and lack of effective communication among program offices concerning applications for support have worked to the disadvantage of many university applicants. ER relies almost totally on unsolicited research proposals; other program offices consider support for university research almost entirely in conjunction with competitive solicitations; and several program offices are not prepared to consider unsolicited proposals at all.

2.1.4. Communication of DOE research interests and priorities

Responses received by the Panel from university scientists indicated particularly strong concern about this lack of procedural consistency among the various DOE program offices in support of university research and about the paucity of current information concerning the Department's research interests and priorities. Several university respondents also commented on the apparent lack of understanding by some DOE program managers of the requirements universities face in carrying out research as part of an academic program, particularly the stability and continuity required for graduate research. Notwithstanding the understandable effects of recent Administration policy changes on energy R&D programs and budgets, the constant sense of instability in the planning and conduct of energy programs has severely affected the "predictability" of university funding. There is a widespread perception that

some DOE programs were interested only in "quick fix" R&D rather than a balanced research program involving long-range, fundamental research, as well as applied research and exploratory development. It is felt many university research groups can contribute to most phases of energy R&D but are not being provided the opportunity to do so.

2.2 Concerns and Comments

The decentralization of university support to the various program offices, the varying procedures used to review and support university projects, and the lack of an agency-wide policy on the role of universities and university scientists in energy R&D have limited progressively the Department's liaison with the university community.

2.2.1 Policy on university roles in DOE programs

Based on the correspondence and presentations to the Panel, it is obvious that university scientists do not see one "Department" but many "Departments" of Energy. From the university perspective, DOE is composed of a number of seemingly autonomous R&D programs, field offices, and contractor-operated research facilities. The university perception of other Federal agencies (NSF, the various R&D organizations in DoD, NASA, and the National Institutes of Health) is substantially different. These agencies are seen to have an agency-wide and uniform appreciation of the roles and importance of universities in their respective programs and the ability to communicate their research interests and priorities in a timely fashion.

Why is the situation in DOE different? The Panel is convinced that a major reason is the lack of a coherent and clearly articulated policy regarding the appropriate roles of university scientists and engineers in DOE programs. This problem is compounded by a lack of comprehensive and timely information on DOE's R&D needs, goals, budgets, and schedules. Whereas programs in ER, particularly such "national trust programs" as High-Energy and Nuclear Physics, have formal advisory committees with significant participation by university scientists, many other DOE programs have little or no formal continuing communication or involvement with the academic community.

2.2.2 University involvement in long-range planning

One recurring theme in most of the university correspondence is concern over the general lack of involvement by university scientists in longer-range R&D planning in Department programs, including decisions on future R&D agendas for each program. This concern is related to others previously expressed in a number of reports from the Energy Research Advisory Board (ERAB) regarding the need for more comprehensive and consistent longer-range R&D planning by DOE programs. It is recognized that planning is difficult in an environment subjected to as many policy shifts and changing emphases as the Department's; nonetheless, such advance planning, including involvement in and discussion by university and other scientists of the roles to be played by each R&D performer—the national laboratories, universities, and industry—could significantly contribute to the development of stronger, more predictable relationships with the external research community.

2.2.3 Support for Historically Black Colleges and Universities

Another issue of specific concern to the Panel is DOE policy regarding support for research and manpower development programs in Historically Black Colleges and Universities (HBCUs). Both Presidents Carter and Reagan have affirmed the need to expand support for the HBCUs. All Federal agencies are supporting HBCU programs in varying degrees. The DOE support of these institutions is also decentralized, with HBCU initiatives being supported in relative isolation in each program office. Some rely on unsolicited proposals from HBCU faculty, some use competitive solicitations, and some use the national laboratories as intermediaries with the HBCUs. The Panel believes that this fragmentation of effort can actually become counterproductive to the strengthening of HBCU participation in main-

stream scientific research. Of the over 100 HBCUs, only a few are now institutionally capable of carrying out major scientific and technical research programs. DOE support should recognize this and concentrate on strengthening the research capabilities of HBCUs chosen for their scientific/technical potential.

2.2.4 Summary

The responses received from university scientists, engineers, and administrators to questions posed by the Panel indicate a high degree of dissatisfaction with the Department's energy R&D programs. The solution to these problems is *not* simply additional funding for university research. Rather, the Department needs to focus on the broader issue of how the capabilities of university faculty and students can be utilized best by the Department, in conjunction with industry and the national laboratories, to meet Departmental requirements and needs. In other words, how can the Department ensure a proper balance of effort among the major R&D performers in each phase of energy R&D?

Our principal recommendation is that the Department, *at the level of the Secretary*, must clearly state its view of the university role in Departmental programs and describe how the Department intends to strengthen and support university involvement in all appropriate activities. A suggested draft of such a policy statement and directive is included as Attachment E. Once such a statement has been developed and disseminated by the Secretary, it will be incumbent upon all DOE programs to adopt practices that ensure conformity with this policy.

2.3 Findings and Recommendations

2.3.1 Findings and conclusions

- There is no overall Departmental policy on the appropriate roles of universities in energy R&D vis-a-vis industry and the national laboratories.
- Universities have significant research and manpower development capabilities that are not being utilized by DOE.
- University researchers do not receive timely and comprehensive information about DOE program plans, interests, and needs.
- Policies and procedures within the Department for the receipt and review of research proposals from university scientists and engineers vary widely and unnecessarily.
- The lack of comprehensive and consistent longer-range R&D planning by DOE programs has led to uncertainties and confusion by university and other scientists regarding program priorities, emphases, and interests.
- The Department has not articulated a policy position on its responsibilities to support the training and preparation of the new professional-level manpower required for future energy R&D programs.

2.3.2 Recommendations

1. The Department should design and implement an agency-wide R&D program planning process to include participation by university and other scientists in decisions on the current and potential role of the major R&D performers (national laboratories, industry, universities) in each DOE program over the proposed planning period.
2. The existing system of DOE advisory panels and peer review groups should be expanded to cover all major R&D programs whether managed at Headquarters, the laboratories, or elsewhere.
3. The Department should establish a DOE-University Forum (similar to the DoD-University Forum initiated in 1982) to enable university representatives to meet regularly with the Secretary and Program Assistant Secretaries on issues concerning university participation in DOE programs (see pp. 30-31).
4. DOE support for research and related programs at the Historically Black Colleges and Universities should concentrate on strengthening the energy-related scientific and technical capabilities of a few competitively selected institutions.
5. The Department should clearly define the roles of university scientists and engineers in support of its R&D and manpower requirements and the Secretary should issue an agency-wide policy directive to

- promote involvement of university faculty and students in all appropriate DOE R&D programs;
- establish the principle that formal advice from university scientists and engineers will be incorporated into the planning and implementation of the Department's research and technology development programs;
- reaffirm the importance of unsolicited proposals from university scientists and engineers as a major means of supporting university-based R&D;
- encourage and provide incentives for interaction and collaboration in R&D among university, national laboratory, and industry scientists and engineers;
- promote participation by faculty and students at the Historically Black Colleges and Universities in Departmental R&D and related programs;
- provide that the need for the continual education or training of professionals in selected research areas should be *explicitly considered* in decisions on where to support energy R&D—at universities, at the national laboratories, or in industry;
- stress the need to commit support to university projects on a time scale that will facilitate graduate and postdoctoral involvement in DOE-sponsored R&D;
- mandate that administrative and reporting burdens on university projects be held to the minimum level consistent with the Department's financial and program oversight responsibilities; and
- designate the responsibility for oversight of university programs, including reviewing the level of university involvement and participation in planning and implementing all DOE R&D programs, to an appropriate senior official in the Department.

3. DOE MANAGEMENT AND PROCUREMENT-RELATED POLICIES IN DEALING WITH UNIVERSITIES

Issue: The Department's management procedures for R&D, including procurement, are burdensome and internally inconsistent and have not been conducive to the development of close working relationships with universities and colleges.

DOE should take all necessary steps to ensure that its management and procurement policies and procedures for R&D are uniform among the program offices, are as simplified as legally possible, and are as compatible with and supportive of university participation as are those of other Federal science- and technology-based agencies.

3.1 Introduction

The Panel's questioning of the academic community elicited extensive criticisms, suggestions, and recommendations concerning DOE's relationships with universities, covering the entire range of administrative and procurement procedures including solicitation, handling, and review of proposals; negotiation and execution of contracts and grants; and financial and technical reporting requirements.

The following excerpts from two letters written by senior university research administrators epitomize most of the communications received:

> — A recurrent theme in discussions of the university/DOE relationship is the increasing difficulty of dealing with the agency on administrative matters. The hassle factor in negotiating contracts, obtaining routine approvals and documenting expenditures has grown in AEC/ERDA/DOE much more than in other agencies. . . . The type of accountability demanded in short-term energy development projects is being extended to basic research to a greater extent at DOE than at other agencies.
>
> — DOE procurement policies are notorious for their slowness and bureaucratic complexity. No other department recommends that simple renewal proposals be submitted more than 120 days in advance of the expiration date of existing contracts. In a one-year cycle, this means that renewal documentation must be prepared on less than two-thirds the funded effort. Frequently, this is before significant results can be obtained. We are driving a car by looking out the back window.

3.2 Support Mechanisms and Procedures

To understand better how the Department's mechanisms and procedures for support of university R&D evolved to the present unsatisfactory state and to suggest corrective measures, the Panel reviewed the history of this subject in the predecessor agencies and programs that were incorporated into DOE when it was established.

3.2.1 Grant and contract mechanisms

The Atomic Energy Commission (AEC) was quite effective in supporting and administering university-based research principally through the means of a unique contract instrument now called the Special Research Contract (SRC); the SRC is a streamlined agreement, much like a grant, to reimburse universities

for the cost of basic or applied research. A relatively simple document, typically consisting of 3 to 5 pages of specific text with 20 to 25 pages of appendixes, the SRC is flexible, calls for minimum reporting, provides for advance funding when needed, and is easily renewed. (A number of university respondents noted that the SRC is even easier to administer than grants for similar projects.) AEC also pioneered the approach of delegating the negotiation, execution, and monitoring of its research awards to individual institutions to one of its field offices, leading to a single continuing point of contact for university administrators and AEC contract officials. In practice, the Chicago Operations Office became the major administrative interface between the AEC and most of the university community up until the mid-1960s.

With the establishment of the Energy Research and Development Administration (ERDA) in 1975, new research areas were added to the nuclear responsibilities of AEC, and with the transfer of these programs came additional personnel with different concepts of university research support. For example, the Solar Energy staff came predominantly from NSF, where university research was supported by grants. Staff in Fossil Energy was drawn largely from the Office of Coal Research in the Department of Interior, where cost contracts were prevalent. The Fossil Energy program staff was also accustomed to centralized procurement based in Washington, although a number of university projects were funded through the Energy Technology Centers in Pittsburgh, Morgantown, etc. Meanwhile, the basic research programs of ERDA continued to use the SRC to support university research projects. (Additional information on DOE's university-related procurement and administrative procedures may be found in Volume II, Chapter 4.)

Shortly after the establishment of DOE in 1977, a working group commissioned by Dr. Frank Press, then Director of the Office of Science and Technology Policy (OSTP), and chaired by Dr. Solomon Buchsbaum of the Bell Laboratories, reviewed the scope and quality of the new Department's basic research programs. Among other things, the group's report called attention to the relatively low level of university support and pointed out the dangers to future university involvement in DOE programs inherent in the increasing disparities in the procedures used by the various component programs of this new "conglomerate" for soliciting and reviewing university proposals and for supporting and monitoring academic research. The principal concerns of the OSTP report in this area were as follows:

> We have noted . . . that the existing DOE research is not well balanced between DOE Labs, industry and universities, with the level of university research in energy-related studies being especially meager. Accordingly, we recommend that
>
> *the budget for basic research in the universities be increased. If necessary, funds should be diverted for this purpose from the development activities or even from other parts of the basic research program.*
>
> Review and procurement procedures for basic research proposals, in many sectors of DOE, are not well organized, are overly involved, take too long and often produce considerable antagonism. This situation need not be since acceptable procedures exist within the OER and elsewhere in the government. Therefore,
>
> *quality control and rapid review-approval procedures for research proposals should be devised and adopted throughout the department.*
>
> The OER should devise review and procurement procedures for research throughout DOE, with the aim of establishing uniform, rapid, and simplified methods. Submission procedures should be well publicized. Review and approval should be accomplished within six months of submission. In general, grants rather than contracts should be used as the supporting mechanism for basic research projects.

These recommendations, despite some efforts to do so, were not implemented effectively; had they been adopted, the present report would probably have been unnecessary.

Instead, diversification continued in the Department's university procurement-related processes: some programs expanded the use of grants while others assigned lead mission responsibilities to national laboratories, which in turn subcontracted with universities for portions of these mission assignments. There

has also been a continuing delegation of responsibility for negotiating, contracting, and monitoring university awards to individual DOE Operations Offices without regard for preserving the original single point of administrative interaction for each university. This is shown in Table 3.1, which summarizes for FY 1982 the award actions taken by each of the several Operations Offices.

Table 3.1. Department of Energy university contract actions[a] for FY 1982 by procurement office

Office	Number of actions	FY 1982 obligations (thousands of dollars)
Chicago Operations	1,762	561,858
Oak Ridge Operations	622	55,868
San Francisco Operations	516	891,973
Washington Procurement	308	11,993
Albuquerque Operations	161	554,422
Idaho Operations	131	5,250
Richland Operations	104	8,366
Nevada Operations	86	11,115
Savannah River Operations	83	7,523
Others (Power Marketing Administrations, Strategic Petroleum Oil Reserve, etc.)	12	3,000
	3,785	2,111,368

[a]Includes both individual university grants/contracts and operating contracts for government-owned laboratories.

Source: DOE Assistant Secretary for Management and Administration.

The gradual blurring of DOE-university administrative contacts has occurred on a program-by-program basis: most university research awards by ER are still handled through Chicago. The Defense Programs use the Nevada and Albuquerque Operations Offices, as well as making awards through the weapons laboratories; Fossil Energy employs both the Washington procurement office and the Pittsburgh and Morgantown Energy Technology Centers for administering university research projects; the Conservation and Solar programs tend to use the San Francisco Operations Office for university projects; and, finally, many smaller education projects of ER and other program offices are handled by the Oak Ridge Operations Office. Furthermore, some field offices use SRC; others use cost contracts; and still others use the grant mechanism for support of research in universities. Small wonder that universities complain about a lack of consistency among programs and field offices in administering awards for research!

3.2.2 Proposal submission and reviews

DOE procedures prescribe that all unsolicited research proposals from university scientists and engineers should be submitted to a central location in the Washington procurement office. In practice, the broad decentralization of responsibilities for university research among Headquarters, the field Operations Offices and the DOE national laboratories has often led to confusion on the part of university scientists and administrators on just where formal proposals should be submitted.

Proposal review procedures also vary widely, ranging from external review panels, mail peer review, in-house staff review, and review by a combination of in-house staff and scientists at the national laboratories. These variations in review procedures are not adequately described by DOE in communications with academic institutions.

3.2.3 Management and reporting

Much concern was expressed about the increasing tendency in DOE to place more management and reporting requirements on university research projects. For example, several of the technology programs require monthly technical and financial reports on each project. In contrast to this approach in DOE, NSF has recently taken steps to reduce significantly the administrative burden for its university grantees through such steps as allowing grantee institutions substantial authority in administering NSF grants. This includes allowing preaward costs, transferring funds from one related NSF grant to another and unilaterally extending the expiration date of an award for up to six months. In contrast, numerous complaints were cited to the panel concerning the laborious and lengthy DOE process for seeking and receiving approval to purchase equipment, to reallocate project budgets, or to extend or renew DOE awards. This has led in a number of cases to universities having to absorb, on an internal basis, the

necessary costs to continue research programs until such time as the DOE award is executed.

3.2.4 Summary

In the final analysis, scientists, whether in universities or in other organizations, need the freedom and flexibility to carry out research in an open and supportive administrative environment. Nobody wants to have creative people spend most of their time continually justifying or rejustifying what has already been agreed to at the outset of the project between the government's technical sponsor and the university. Yet, this seems to be what has happened too often in DOE-sponsored university research. The Panel feels strongly that the Department should make strenuous efforts to reduce the "hassle level" of the administration of university research projects. At the same time, the Panel clearly understands the need for close monitoring of university projects that include applied or early demonstration type work or the operation of major research facilities. If a university research group is selected to carry out such major applied programs, it should be subject to the same reporting and administrative requirements as other contractors.

The Panel believes that the type of administrative controls applied to basic research can affect the quality of research being performed. The Panel urges the Department to explore ways to simplify and make consistent the management and administrative procedures used to support university research. These steps should reduce the diversion of time, effort, and cost away from the central purpose of carrying out advanced research. Simplifying procurement policies and procedures and reducing paperwork are not inconsistent with sound management or auditing procedures, but rather can encourage the best research efforts along with the earlier availability, understanding, and dissemination of research results. Finally, the Department's university procurement policies and procedures can influence whether or not university scientists even seek support from DOE. One respondent to the Panel survey summarized the feeling on the part of scientists at his institution regarding DOE support in the following way.

> Our faculty often prefer to seek support for basic energy-related research from other Federal agencies, particularly the Department of Defense, principally because of the more open and flexible administrative environment in the support of such research. Research carried out with DoD support, for example, may be quite relevant to energy R&D needs as, for example, in materials research, corrosion studies, control systems, etc. The loss to DOE, however, is that such faculty members are not directly involved in or oriented towards energy R&D needs. The nation may benefit as part of this process, but in at least the short term, the Department is the loser in the sense of being cut off from some of the most creative minds on university campuses.

If, as consistently stated by senior DOE program staff, it is the Department's intent to support the best qualified researchers regardless of their organizational location, then the Department's current university-oriented procurement and administrative policies and procedures must be significantly improved.

3.3 Findings and Recommendations

3.3.1 Findings and conclusions

- There are significant inconsistencies between DOE program offices in the handling and review of university research proposals.
  - — Some programs totally rely on unsolicited proposals; others do not.
  - — External peer review is used by some programs; in-house staff review (including national laboratory staff) is used by others.
- The selection of an appropriate award instrument by DOE program offices for the support of university research seems to depend more on the program's tradition and history rather than on the nature of the work being supported.
  - — Some programs use scientific research contracts to support university research; others use grants or "cost-type" contracts for similar research.
  - — Some university awards are multiyear, whereas others for similar research must be renewed annually.
  - — Award execution responsibilities are delegated by DOE to ten offices/technology

centers, with universities often having to deal with many different DOE procurement offices at the same time.

— University scientists and administrators report increasing concern over what is perceived as the growing complexity and related administrative overmanagement of DOE research awards.

3.3.2 Recommendations

1. The Department should undertake a review and evaluation of the appropriateness of the university proposal review procedures used by each major DOE program with the objective of ensuring conformity. The results of this review (and the procedures used by each program office to review university proposals) should be widely distributed in the academic community.
2. The Department should strongly reaffirm the importance to the Office of Management and Budget, the General Accounting Office, and the appropriate congressional committees of university unsolicited research proposals in the support of innovative research on longer-term problems.
3. The Department should reaffirm the policy (stated in DOE Order 4210.4) that unsolicited research proposals should be formally submitted to one central proposal clearinghouse in Washington and that universities should normally deal with only *one* field procurement office for all awards from DOE as prescribed in DOE Order 4200 (excluding, as necessary, defense-related university support or other special programs).
4. In the absence of more extensive use of grants, the Department should take concerted action to retain the special authority to use Special Research Contracts to support university research projects, and the SRC instrument should be used by *all* DOE procurement offices.
5. Multiyear research awards should be used increasingly by DOE to ensure stability and continuity in university funding.
6. The reporting and administrative requirements on university research projects should be simplified and conform to the experiences and practices of other Federal agencies (including DoD, NASA and NSF).
7. Periodic meetings should be held between senior DOE procurement and program staff and representatives of the university research administration community to exchange views on methods of simplifying the Department's university procurement and assistance policies and procedures. These discussions could be tied to the DOE-University Forum described on pp. 30–31.

4. RELATIONSHIPS BETWEEN THE DEPARTMENT'S NATIONAL LABORATORIES AND THE UNIVERSITIES

Issue: A widespread perception exists in the academic community that the Department's national laboratories have an unfair institutional advantage in obtaining DOE support in some areas.

The Panel is concerned about the difficulties that have arisen in the relationships between the Department's national laboratories and the academic community because of such concerns as the allocation of research funds by the Department and confusion over the appropriate roles of each performer in carrying out Departmental programs. The Panel strongly recommends that the Department take appropriate actions to address these difficulties and strengthen the ties between the national laboratories and the universities.

4.1 Introduction

The Department of Energy manages 50 contractor facilities that collectively employ over 50,000 scientists and engineers and receive over 50% of the Department's R&D budget, with about half of this amount for weapons R&D. Nine of these contractor facilities are classified by the Department as multiprogram national laboratories. The Department's national laboratories are federally owned and funded facilities managed and staffed by private contractors, including, in a number of cases, universities and university consortia. Research programs, particularly at the multiprogram laboratories, range in size and nature from small, project-type research in most of the basic energy science-related disciplines to large, multidisciplinary, technology-oriented research programs and major weapons R&D involving teams of scientists, engineers, and support personnel and the operation of various unique user research facilities. There is wide diversity among the individual national laboratories in terms of their mix of program responsibilities and facilities, their involvements in various phases and areas of energy R&D and, indeed, in their operational "styles" and characteristics.

The roles and missions of the Department's multiprogram national laboratories were extensively studied by ERAB in a report published in September 1982. This report recommended that the Department undertake a series of steps to improve the usefulness of the laboratories as national resources, including expanding the already significant cooperation between the laboratories and the university community in the training of scientists and engineers at laboratory facilities. The recommendations made in the laboratory study are currently under review by senior staff in the Department. The University Programs Panel did not reexamine the question of the proper roles and missions of the national laboratories but rather attempted to ascertain how the relationships between the laboratories and the university community could be strengthened and expanded.

4.2 Concerns and Comments

4.2.1 Relationships between individual scientists

The relations between the Department's national laboratories and the university community received the most intense comments

from university scientists and administrators. (These relationships and the concerns raised by university scientists/administrators regarding the national laboratories are examined in more detail in Volume II, Chapter 3.) These concerns reflected two different perspectives. First, there generally seem to be minimal problems in the relationships between individual scientists at universities and their counterparts at the national laboratories. This varies, of course, by scientific field (there is certainly no question about the very close relationships between high-energy physicists in universities and at the national laboratories.) Favorable comments regarding the laboratories were received particularly from faculty at smaller colleges, whose interactions with the laboratories often represent their only contact with advanced research.

4.2.2 Competition for DOE support

From higher up in the university hierachy, however, substantially different opinions were voiced about the national laboratories. The relationships between the Department and the external R&D community principally revolve around the allocation of money for R&D. In tight budget times there is simply not enough to go around. This is understood by all involved in energy R&D. There is, however, a widespread perception in the university community that the national laboratories, at least in certain fields, have an unfair institutional competitive advantage in receiving support from the Department. This is explained by some respondents as one result of the long-standing and historic working-level familiarity that laboratory scientists have with their counterparts in DOE. Partly because of this the funding process is perceived to be substantially easier for the laboratories than for the university community. The perception is also widespread in the university community that the different review criteria and procedures used by DOE for laboratory research proposals are different from those for university research projects. Proposals submitted by university scientists are subjected to extensive in-house and peer review (a process that normally takes at least six months), whereas the perception is that laboratory research proposals for *similar types of research* have a much easier and quicker route to follow.

4.2.3 DOE's placement and management of research facilities

The Department has recently located a number of new research facilities at the laboratories. The processes used to decide what types of new research facilities are needed and where they should be located are not generally well understood by the academic community. Several respondents cited the recent example of the Lawrence Berkeley Laboratory National Center for Advanced Materials as a case where the Department did not adequately consult with the scientific community before proceeding. Conversely, many respondents recognized and endorsed the unique roles played by the laboratories in the management of major research facilities (e.g., the National Synchrotron Light Source at Brookhaven). These facilities are directly beneficial to university faculty and students carrying out research. The laboratories are also recognized as having an important role in assisting in graduate education and training, particularly through the participation of graduate students in laboratory research programs and through the use of laboratory facilities and instrumentation.

4.2.4 Collaborative research programs

University respondents also felt that the laboratories have little or no incentive to develop collaborative research programs with university scientists (not just subcontracts). The perception is that many university/laboratory research projects tend to be on terms established by the laboratories themselves and are not *true* collaborative efforts with joint planning and implementation.

4.2.5 Laboratory institutional plans

Another widespread viewpoint in the university community is that because the laboratories are required to prepare long-range institution-wide research plans, they are able to provide the Department with early warning of laboratory interest in new or expanded research programs and facilities. Therefore, the laboratories, according to university critics, have an

"inside track" in submitting proposals to the Department for inclusion in the Department's own budget proposals.

The comments received from university scientists and administrators on this issue reflect, in part, the relative lack of information in the university community about the role, missions, and organizational procedures used by the DOE national laboratories. There is relatively little understanding in the academic community of the laboratories' activities, their means of support, their management relationship with the Department of Energy and, indeed, their entire process for the development of new research programs for review by DOE. The laboratories, after all, are federally owned and funded facilities. They are "creatures" of the Department, not the other way around. The criticisms, therefore, expressed by many university scientists on the roles of the national laboratories are more properly addressed to DOE, not the laboratories.

4.2.6 Summary

The real issue is whether the Department is properly seeking out, encouraging, and supporting all qualified researchers and research groups, regardless of their institutional affiliation, in energy R&D and related programs. The crux of this matter was summarized in a letter from the president of a major research university.

> The matter of mutual trust and predictability is also, I think, at the root of the troubling and growing perception among university faculty that the national laboratories have an unfair advantage in the competition for DOE research dollars. This is unfortunate, because the laboratories and the universities each have 'national trust' missions and each must be supported. . . . I believe that mutual trust and understanding will develop only if the universities, especially in their relationship with the national laboratories, come to view themselves as having a shared community with DOE.

The relationships involving DOE, the laboratories, and the university community are complicated, extensive, and hard to generalize. So are the potential approaches to strengthening these relationships. It is not the intent of the Panel's report to make explicit policy recommendations to DOE on the balance of funding that should be provided to either the laboratories or the universities. These are decisions that must be made first at the individual program level and then reviewed and approved at the Departmental level. In general, however, the Panel believes that DOE program and policy staff have not sufficiently understood and appreciated the different strengths and capabilities of the university community, as contrasted to those of the national laboratories, in relation to DOE program needs. The laboratory and university communities are complementary to a great extent—in research interests, the need for decentralized state-of-the-art research facilities, etc. However, there are important differences, not the least of which is the preeminent responsibility of universities for professional manpower development. The Department needs to clearly articulate the roles of the major R&D performer sectors in carrying out Departmental programs. The suggested DOE-University Policy Statement (discussed in Chapter 2 and included as Attachment E) is another step towards this articulation.

4.3 Finding and Recommendations

4.3.1 Findings and conclusions

- The Department's major multiprogram and program-dedicated national laboratories are important, often unique, national resources for advanced scientific and technical research.
- Universities have unique responsibilities in the preparation of new professional-level manpower for future R&D careers, a process that must be done in an advanced research environment.
- In accord with a previous ERAB study, the Panel agrees that the appropriate roles of the national laboratories as performers of energy R&D should be clearly defined vis-a-vis universities and industry.
- The national laboratories provide essential support to university-based research through the operation of unique, user-oriented research facilities and by providing assist-

ance in the training and preparation of students for future careers in energy R&D.

- Strong concerns have been expressed by university administrators over the perception that the national laboratories have an unfair competitive advantage over the university community in receiving support from the Department for new research and related facilities/equipment because of historic institutional ties to the Department and close working relationships with Departmental program managers.
- The lack of policy guidance from the Department has hindered the development of collaborative research programs involving university, national laboratory, and industrial researchers.

4.3.2 Recommendations

1. Research proposals submitted to the Department should be subjected to comparable standards of external peer review regardless of performer even though the mechanisms of proposal review may vary from program to program and performer to performer; the policies and procedures used by the Department to authorize and support new research work in the DOE laboratories should be summarized and widely distributed to the academic community.
2. Laboratories assigned lead mission responsibility by the Department for the management of applied research programs should be given greater discretion in the allocation of resources and in the selection of performers. The allocation of research funds should be based on a careful system of peer review that draws on the best scientific and technical advice available nationally to ensure that scientific/technical merit is the prime consideration for funding from the laboratories.
3. The Department should develop policy guidance and explicit incentives to encourage the development of collaborative research programs involving university, laboratory and industrial researchers.
4. Significantly expanded support should be provided for faculty and student research training appointments at the national laboratories, including sabbatical year-type faculty appointments and postdoctoral research.
5. Annual institutional planning-level reviews carried out at each laboratory by DOE staff should continue to include an explicit evaluation of each laboratory's relationship with and programs for university faculty and students.

5. UNIVERSITY PARTICIPATION IN ENERGY TECHNOLOGY R&D

Issue: University engineering and applied science groups are not given adequate opportunities for participation in the Department's energy technology development programs.

The capabilities of university scientists and engineers to contribute to shorter-term, applied research programs should be more adequately recognized and supported by each major technology program office.

5.1 Introduction

University funding provided through the Office of Energy Research is characterized essentially by a focus on long-range, discipline-oriented basic energy research with substantial stability of funding for each university project (ranging from 3 to 7 years per project and averaging about $90 thousand per year). Support provided through the various energy technology programs in the Department (Fossil Energy, Solar and Renewable Energy, Nuclear Energy, etc.) is characterized, in general, by a shorter-term research focus and is dominated by the need to clearly establish technical proof of concept so that follow-on work might be carried out by appropriate private sector performers.

5.1.1 Fossil Energy Program

University participation in the various energy technology programs for university research varies widely. For example, the Office of Fossil Energy has, for a number of years, sought to broaden the base of university research participation in coal conversion and utilization. One special program called the University Coal Research Program was developed for this purpose. Each year the program released a Notice of Program Interest (NPI) listing a number of research areas for university scientists. Unsolicited proposals are prepared by interested faculty and submitted to the Pittsburgh Energy Technology Center for peer review. About 70 projects are currently supported through this program. The process followed by the University Coal Research Program is a potential model for other technology programs to consider in supporting university-based technology-oriented research.

5.1.2 Nuclear Energy Program

In the Office of Nuclear Energy, out of a total $3.5 billion annual program, about $3 million per year is made available for university nuclear technology-related research. This support is provided primarily through the various national laboratories that have major programs in nuclear energy. No special programs have been developed specifically to encourage university research participation in nuclear energy. Support provided for what might be defined as classical nuclear engineering research involving faculty and students has been particularly limited from DOE. This is the type of research that is focused on conventional and improved reactor technology. In general, nuclear engineering students are involved, not in the study and development of new technical concepts, but in research on risk assessment and safety-related issues. The

Nuclear Regulatory Commission actually funds more research with university nuclear engineering departments than does the Department of Energy. These departments seem almost totally "isolated" from involvement in reactor technology R&D. The Office of Nuclear Energy has, however, made a special emphasis in the past several years to increase the number of graduate students pursuing doctoral degrees in nuclear science, nuclear engineering, and health physics. A graduate fellowship program was initiated in FY 1980 to support about 20 graduate students per year in these three areas. A similar effort is supported through the Fusion Energy Program.

5.1.3 Conservation, Solar, and Renewable Energy Programs

University involvement has also been limited in scope and nature in the conservation, solar, and renewable energy programs of the Department. A small number of university projects in conservation R&D have been supported (about 20 in FY 1983). As is the case with nuclear energy, many of the projects supported through the conservation programs have been funded through one or more of the DOE national laboratories. The solar and renewable energy programs have provided varying degrees of support for university research in most relevant fields (photovoltaics, biomass, geothermal, etc.). In prior years, many of these projects were funded through the Solar Energy Research Institute (SERI) in Colorado. Budget reductions at SERI in recent years, however, have essentially eliminated this support for university subcontracts in favor of in-house research. About 40 university awards were supported in the solar and renewable energy programs in FY 1983.

5.2 Concerns and Comments

5.2.1 Sources of support and grey-area proposals

There is a perception in the university community of a significant gap between the support for university research provided through the research programs in ER and the development-oriented support provided from the technology programs. Submitted proposals that fall in a grey area between basic research and applied research/exploratory development seem to have had significant difficulty in being funded. According to several university respondents, this situation has required them to prepare and focus their research on the specific interests and priorities of the program offices with potentially the most interest in their research. This tailoring may or may not reflect a real appreciation of the type and nature of research that would be most appropriate in each area. A number of respondents to the Panel's survey also indicated concern about the lack of support for manpower development and training in the technology programs even though industry and the Department's own laboratories have a very high demand for people who have received sound preparation in technology-oriented research.

5.2.2 Joint university-industry projects

One approach used by other Federal agencies to support technology-oriented research involving university scientists, while at the same time training graduate students in applied R&D, has been the funding of joint university-industry research projects. The NSF has been particularly active in promoting and supporting such joint activities. NASA and DoD have also supported a number of joint university-industry efforts. Such joint projects have the dual benefit of providing university faculty and students with the opportunity of learning about the specific R&D needs of industry while at the same time enhancing and expediting the application by industry of university-generated basic research concepts.

DOE has in the past supported a small number of joint university-industry projects. These have not occurred as a result of an agency-wide interest in or focus on such joint efforts but rather in response to "local" situations in various DOE program offices. DOE involvement in university-industry projects is described in more detail in Volume II, Chapter 5 and the appendixes. This includes several case studies on past and current projects. One pilot effort by DOE involving the Ford Motor Company and three universities is of particular interest to the Panel as a potential model

for similar projects. The Ford case study points out the advantages and benefits to both the industrial group and the participating universities while at the same time describing the difficulties the project had, over time, regarding support and interest from DOE. The Panel believes that the benefits of joint university-industry research in energy technology R&D are significant to all parties concerned, including DOE, and that the Department should make a concerted effort to stimulate and support such projects in the future.

5.2.3 University-based engineering research and education

The Panel was particularly concerned about the impact of DOE support on engineering research and manpower development. Therefore, deans of twenty major engineering schools (in terms of research support, number of students, etc.) were asked to comment on this and related issues and concerns. (A detailed analysis of these responses is included in Volume II, Chapter 2.) In general, the responses indicated that, except at a few locations, the resources of these schools have been clearly underutilized by DOE and that research programs have had no significant impact on the "intellectual resources" of engineering faculty and students. This underutilization was pointed out to have significantly limited the development of new talent needed to carry on future technical R&D programs. This is particularly noticeable in nuclear engineering according to survey respondents.

The general lack of support by DOE of engineering-oriented research and education exists in sharp contrast with DOE's impact on research and education in physics, chemistry, materials sciences, and other basic science fields as influenced by the ER programs. According to aggregate data from NSF, DOE does rank second in Federal agency support of university engineering R&D. Much of this funding on closer examination, however, was provided to several large "predemonstration-type" projects, such as magnetohydrodynamics and fluidized-bed combustion R&D, that were generally conducted outside of the engineering schools and departments and involved significant numbers of nonteaching researchers. The dean of one leading engineering school pointed out that DOE ranked sixth, possibly seventh, in comparison with NSF, DoD, private foundations, and others, in the support of engineering research on his campus.

Respondents pointed out that the lack of DOE support for engineering research is due essentially to two factors. One is that ER has not established a firm position on the support of engineering (applied) research vis-a-vis research in the basic sciences. The second is the perception (as noted before) in several, although not all, of the technology-oriented programs that university research can contribute little, if at all, to both short- and longer-term R&D requirements.

Within DOE, support for university-based engineering research has been provided primarily by the Fossil Energy Program and by the Engineering Research Program in the ER Basic Energy Sciences Program. This latter program supports about 20 university engineering projects each year. It has not, however, had a sufficient budget ($6.4 million in the FY 1984 budget request) to make a significant impact. Other engineering research projects supported by the various energy technology programs have been significantly affected, as already noted, as a result of overall budget reductions.

The Panel notes again that this subject has been addressed before by various review and study groups including the 1978 Buchsbaum OSTP Panel. Again, it is illustrative to cite a pertinent section of this report:

> The Panel holds the view and, we believe, key members of the DOE agree, that the OER should not have total responsibility for the management and support of all basic research within the DOE. For an efficient flow of ideas from basic research into the technology programs, the two must be closely coupled through applied research and exploratory development. The coupling must be such that the longer-term basic work is not preempted by short-term needs of the technology programs in which the basic work is embedded. Therefore, if basic research is to be an effective element of the technology programs,
>
> *it is essential that each Assistant Secretary assume responsibility for the funding of basic research that is relevant to his program objectives.*

Basic research must be supported by all of the Assistant Secretaries within their own operating budgets as integral components of their RD&D programs. The extent to which this is now done is inadequate. The needed levels of long-term basic research within the divisions performing RD&D will differ with program objectives and program status, but the research must be of significant magnitude and have sufficient quality and perspective to assure both an adequate response to short-term program-implementation goals and the vitality of the disciplinary areas crucial to the development programs.

The fact that ER now provides nearly 80% of the Department's total direct funding of university R&D means little progress has been made in achieving a proper balance of support and involvement of university researchers in technology-oriented R&D.

5.3 Findings and Recommendations

5.3.1 Findings and conclusions

- University funding from the energy technology programs is characterized by a short-term focus; unpredictable, often unstable funding; and uneven distribution by technology.
- Inadequate funding from DOE has deterred university engineering schools from helping to achieve DOE program goals and has limited the number of engineering graduate students being trained in energy technology-oriented R&D.
- There is a widespread perception in the academic community of an agency-wide lack of interest in engineering and applied science research.
- The limited support for university nuclear engineering research is of particular concern to both university nuclear engineering departments and the nuclear technology industry.

5.3.2 Recommendations

1. Each technology program office should explicitly recognize its responsibility to support university-based research related to specific technology needs. Consideration should be given by each technology program to ways in which university participation in technology R&D can be increased.
2. The Engineering Research Program in the Office of Energy Research should be significantly increased in size and scope over the next five years, including the initiation of a new program of research support for younger faculty members in engineering.
3. Support should be provided to increase the numbers of engineering/applied science students, including the use, as appropriate, of competitive graduate fellowships in selected fields.
4. Joint university-industry research and related manpower development projects should be encouraged and supported in each energy technology program.
5. Expanded support should be provided for university nuclear engineering research, perhaps coupled to joint funding with nuclear-related industrial companies.

6. THE DOE ROLE IN THE DEVELOPMENT OF NEW PROFESSIONAL MANPOWER

Issue: The Department has increasingly limited its support and funding for the training of new scientists/engineers.

The Panel recommends that the Department explicitly reaffirm its responsibilities to help ensure that sufficient numbers of highly qualified scientists and engineers are available to meet current and future national energy R&D needs.

6.1 Introduction

6.1.1 Supply of professional manpower

The question of what an adequate supply of professional manpower for energy R&D is cannot be isolated from broader national needs for scientific and technical manpower. Currently, there are major concerns in the Administration (as well as in the private sector) regarding the availability of sufficient numbers of suitably qualified scientists and engineers to meet both present and projected R&D needs. Statistics on the number of students pursuing advanced degrees in engineering are of particular concern to the R&D sector. This situation is summarized in Volume II, Chapter 1.

Other energy-related scientific/technical disciplines that are facing similar problems of enrollment declines at the graduate level include geophysics, nuclear science, radiation chemistry, and health physics. The overall scientific/technical manpower situation may be further exacerbated by the projected 25% decrease in the number of 18 to 24 year olds by the early 1990s. This means that the ratio of science and engineering students to students in other academic areas must be significantly increased by that time if only to maintain today's numbers.

6.1.2 Roles of Federal agencies in manpower development

Major responsibilities for carrying out the Federal role in professional manpower support and development clearly rests with NSF and the Department of Education. Both these agencies are developing new manpower-oriented initiatives, including support for precollege-oriented programs as well as support for college-level activities. The President's Science Advisor on numerous occasions (including a presentation to the Panel), however, has specifically stated that the Federal mission R&D agencies must also play an important, complementary role in this process.

These mission agencies have, over time, carried out their manpower development responsibilities in ways particularly suited for their own missions; for example, the National Institutes of Health has consistently provided support for large numbers of graduate fellowships in the biomedical and health-related sciences. The Department of Agriculture, through the various agricultural extension and land-grant university programs, has closely interrelated student support to agricultural research. NASA has for years maintained a special concern for ensuring adequate numbers of scientists and engineers in the aerospace-

57-279 O - 87 - 51

related fields. The DoD, through the three military services, has sponsored a number of special programs over the past several years focused on ensuring that an adequate supply of scientists and engineers will be available to carry out future defense R&D programs. For example, the Office of Naval Research has provided support each year for a small number of graduate fellowships in disciplines directly relevant to naval R&D. The stipends for these fellowships have been set at a competitive level to encourage undergraduate students to pursue advanced degrees in the various areas. In addition, all three services have supported summer research and cooperative intern programs at a number of the DoD laboratories for both high school students and undergraduate students.

DOE has similar needs for highly skilled scientific and technical specialists in all the disciplines that are the foundation of energy R&D. Future scientific and technical advances in all energy research and technology development areas will depend in large part on the availability of new and well-prepared scientists and engineers. The principal and by far the best way the Department can support the preparation of new manpower is to provide adequate funding for campus-based research projects directly involving graduate students. This approach is strongly endorsed by the Panel.

6.2 Concerns and Comments

6.2.1 DOE's role in manpower development

The DOE role in manpower development received many comments from the university community. One respondent from a major public university stated:

> the Department's responsibility for manpower development derived directly from its research mission. Since the Department bears most of the national responsibility for research needed for long-term energy technology development, it must ensure the continued availability of professionals for research since the university is the nation's sole source of energy professionals and research is the means by which they are trained. Adequate support for university research is required in order to provide for future manpower supply. The projected shortage of engineers in a number of energy fields is due in large part to the lack of [DOE] support for engineering research at universities.

Several respondents indicated concern that recent elimination of support by DOE for graduate traineeships/fellowships has impaired the ability of faculty members to recruit bright undergraduate students for participation in advanced energy research. A related issue cited is the "stop and start" problem of university funding from some DOE programs which has, at times, left graduate students "high and dry" because of the abrupt termination of a research project. A graduate student pursuing a Ph.D. degree in engineering and the applied science fields typically takes from three to six years to finish the degree. Stability must therefore be built into DOE support for university projects.

6.2.2 Support at three educational levels

As noted, the Department has been principally concerned with the training and preparation of new professional manpower through the support of graduate students on DOE research projects (primarily in the basic science disciplines of physics, chemistry, materials science, biology, and the environmental sciences). There are essentially three leverage points DOE can use in helping to increase/enhance the supply of professional-level manpower for future energy R&D programs. These are (1) at the secondary school level to encourage additional students to pursue science and engineering academic careers, (2) at the junior/senior level in college to encourage more students to pursue graduate-level degrees and, related to this, (3) at the graduate and postgraduate level to provide additional incentives for graduate students and postdoctoral researchers to become involved in energy-related advanced research.

In the past, DOE and its predecessor agencies have conducted special training programs in each of these three areas. For example, AEC initiated support for a range of training programs in the nuclear sciences for high school students and teachers. ERDA and DOE continued this practice both through the support of summer institutes for high school teachers on energy and in the preparation of instructional

materials on energy research and development for use in high school science and related courses. Support for high school teacher institutes and instructional materials, however, was discontinued in FY 1982 although some secondary school-related activities are carried out by several of the national laboratories. The Panel believes that the Department should maintain at least a modest degree of involvement in precollege-level education, perhaps with a special focus on women/minority student programs. However, this area is essentially outside the purview of the Panel's charter, and therefore no specific recommendations are made regarding precollege programs.

At the undergraduate level, about 600 undergraduate students are supported each year in summer research assignments at the national laboratories through the ER's University-Laboratory Cooperative Program. This effort is strongly endorsed by the laboratories, and there are at least five applicants for each place available in this program. At the graduate level, DOE has provided modest support for graduate fellowships through both the Fusion Energy and the Nuclear Energy Programs (about 20 graduate fellowships per year in each area.) Also, 57 graduate traineeships were supported in FY 1982 in four engineering disciplines (chemical, mechanical, petroleum, and nuclear engineering). No funds were requested by the Department to continue this targeted training effort in the FY 1983 budget request.

The Department supports approximately 350 postdoctoral researchers each year in the national laboratories, primarily in physics and chemistry. This support is decentralized, with each laboratory responsible for its own postdoctoral programs using research funding provided by individual DOE program offices. This is another area where the Department is not taking full advantage of both available resources and the essential need to keep younger scientists (those within five years of having received the Ph.D.) involved in full-time research at a time in their careers when they need to become fully established as quality researchers.

6.2.3 Summary

The Panel believes that the Department has an important responsibility in the preparation of new scientists and engineers. There are a number of potential mechanisms by which the support can be provided in addition to the funding of on-campus research. These include supporting graduate and postdoctoral fellowships in selected fields of probable relevance to future needs and expanding the use of both the physical and human resources available at the national laboratories for assisting undergraduate and graduate students. The Panel believes that the goal of the Department's manpower program should be to attract more of the best-qualified students into energy-related R&D careers. Overall, however, the focus of the Department's professional manpower efforts should be *quality, not quantity.*

6.3 Findings and Recommendations

6.3.1 Findings and conclusions

- In the past DOE has supported training of new professional-level manpower principally through the funding of university research projects involving graduate students. Such support has been uneven, however, with relatively large numbers of students supported in the basic science disciplines of physics, chemistry, etc., and far fewer students in applied science and in engineering.
- The Department has legislative authority to carry out manpower training at all educational levels, including precollege programs, but has not developed and consistently carried out programs designed to ensure adequate supplies of professional-level manpower for current and future energy R&D programs.
- DOE support for university-based research on technology-oriented problems has often been subject to abrupt program and policy changes and shifts leading to discontinuities in the support of graduate students.

- The national laboratories play important complementary roles to those of the universities in manpower development and training, but the resources of the laboratories in this area have been significantly underutilized by the Department.

6.3.2 Recommendations

1. The Department should explicitly recognize its obligation to play a significant supporting role in the overall national effort to ensure adequate numbers of highly skilled scientific and technical professionals. Given the generic nature of energy as a scientific/technical subject, DOE should ensure that support for manpower development is comprehensive across the major energy-related academic disciplines (the basic sciences, engineering, health and environmental sciences, etc.).
2. The Department should make a policy commitment to the support of graduate students on university research projects; such support should be as stable as possible.
3. The Department should initiate an agency-wide graduate and postdoctoral fellowship program to encourage students to work in areas of interest and relevance to the Department. The students supported should be given the opportunity to participate in research at the DOE national laboratories or with other contractors.
4. Support for the DOE University-Laboratory Cooperative Program should be significantly increased, particularly for undergraduate and graduate student appointments.
5. The Department should place special emphasis on the need to attract more women and minority students into the national scientific and technical manpower pool and provide support for research and related manpower development efforts at selected universities and colleges with substantial women/minority enrollments.

7. COMMUNICATIONS BETWEEN THE DEPARTMENT AND THE UNIVERSITY COMMUNITY

Issue: Universities and university scientists are inadequately informed about DOE program policies, interests, and needs; conversely, there are insufficient means by which university-based advice can be solicited/incorporated in DOE R&D program planning.

Effective two-way communication is essential to good DOE-university relationships. DOE must recognize that such communication is critical at all organizational and program levels, including the national laboratories. Particular attention is needed to strengthen the communications between senior DOE officials and their counterparts in the university community.

7.1 Introduction

All major organizations, whether in R&D or in other fields, face problems of communication internally as well as externally. DOE is no exception. Communications between DOE and the broad university research community are complicated by the multitude of channels including staff and program offices in Washington, field Operations Offices, the national laboratories and other contractors vis-a-vis individual university scientists, university administrators, and university and professional societies and associations.

7.2 Concerns and Comments

7.2.1 Nature and timing of communications

Based on the correspondence received by the Panel, it is apparent that many university scientists and administrators perceive their current communications, such as they are, with the Department as essentially a one-way process, that is, from DOE to the university community. Under many circumstances, even this flow of information seems erratic, with some DOE programs having well-established communications links (e.g., the High-Energy and Nuclear Physics Program or the Fusion Energy Program) while others are lacking these. Another common thread that runs through the correspondence is the lack of opportunity for knowledgeable university scientists to provide advice to DOE program directors at an early stage of the R&D policy formulation and planning process and thus to participate in determining the agenda for future research initiatives. This concern was addressed in Chapter 2.

Universities, however, are a diverse set of institutions as has been noted; there is also diversity among university scientists and administrators. The task of communicating *essential* and *relevant* information to the university community, therefore, requires constant imagination, flexibility, and, most importantly, continued personal contact with both bench-level scientists and senior university administrators.

7.2.2 Other Federal agency–university communications

The Panel examined the experiences of other Federal agencies in handling communications

with the university community. The National Institutes of Health has formal advisory committees that are involved in reviewing and evaluating the research programs and plans of each institute. These committees have major, in some cases total, representation of university researchers. NSF uses both the National Science Board and various other formal advisory committees that serve as communications channels between the university community and the programs within the agency.

The experiences of the DoD in communicating with universities are particularly relevant to DOE. Based on a recommendation to DoD senior management in a 1981 report prepared by the Defense Science Board, a forum of senior university and DoD officials has been established to review and discuss the full range of research-related needs and issues that affect the DoD's relationships with the universities. This forum includes a small number of university presidents and senior officials selected jointly by DoD and the Association of American Universities (AAU), with staff support provided by AAU. Periodic meetings are scheduled throughout the year, with an agenda prepared in advance and appropriate follow-up to resolve issues and questions.

The DoD forum appears to be working smoothly and has helped facilitate consultation with the university community on such key issues as export controls, foreign language study needs, and defense-related basic research requirements. The Panel believes that DOE should establish a similar forum of senior university officials able to represent the broad university community. Such a forum could perhaps initially be organized under the auspices of ERAB.

7.2.3 Summary

There are other steps that can be taken by the Department to improve the quality and focus of communications to and from the university community. These include regularly preparing and publishing an agency-wide guide to DOE-university programs (perhaps similar in format to the annual program guide prepared by NSF) and expanding the number and subject coverage of research planning workshops, conferences, etc., involving both university and other researchers. The Department also needs to improve the dissemination of the results of its sponsored research (regardless of the type of performer) to ensure that other researchers are informed of and are up-to-date on the ongoing research programs and projects funded by the Department. An example of this would be the annual reports prepared by certain DOE programs that summarize ongoing and completed research projects. The DOE Technical Information Center (TIC) in Oak Ridge is a particularly critical resource in this regard to the academic community. TIC collects and abstracts DOE-sponsored research. This information, if more widely publicized and disseminated, would be invaluable to university (and other scientists) seeking information about DOE program interests and activities especially in applied science and technology-oriented R&D. Finally, the Panel notes with approval the recent action taken by the Director of the Office of Energy Research to meet periodically on a regional basis with senior officials of major research universities during scheduled visits to the national laboratories. Other DOE senior staff members should consider developing similar mechanisms that would enable them to meet informally with their university counterparts.

7.3 Findings and Recommendations

7.3.1 Findings and conclusions

- Communications between the Department and university researchers/administrators are too decentralized and inconsistent to benefit both parties.
- The development of effective two-way communications with the academic community has been hampered by the size and complexity of the DOE system.
- Results of DOE-sponsored research, particularly in the applied science and technology development programs, have not been adequately disseminated to both the academic and the industrial research communities.
- Sustained discussions between senior DOE staff and their university counterparts are essential to resolving issues and concerns

and strengthening the DOE-university relationship.

7.3.2 Recommendations

1. Based on the demonstrated effectiveness of the recently established DoD-University Forum, DOE should establish a similar forum of university leaders to meet periodically with senior DOE staff, including the Secretary, on a range of research-related issues affecting the Department's ties with universities. ERAB could be used as an intermediary to help establish this forum.
2. DOE should improve the dissemination of information to universities about DOE program research interests, programs, needs, and facilities.
   - A comprehensive guide to DOE-university programs should be prepared and widely distributed at least every two years.
   - Staff contacts in each major DOE R&D program should be clearly designated to handle university inquiries regarding research needs and policies and procedures regarding university participation and support.
   - The activities of the DOE Technical Information Center should be expanded to include annual publication of summary abstracts of DOE-sponsored research by field, performer, and subject.
3. Increased use of temporary or other term-type appointments should be made to involve university scientists as special advisors/staff in DOE R&D programs.

8. UNIVERSITY INVOLVEMENT IN MULTIDISCIPLINARY AND INTERDISCIPLINARY RESEARCH PROGRAMS

Issue: The extensive multidisciplinary and interdisciplinary research, manpower development, and public extension/outreach capabilities of universities are underutilized by the Department.

The Panel recommends that DOE consider developing a new program initiative to take advantage of the unique resources of research-oriented universities for multidisciplinary and interdisciplinary research by establishing a program of competitive university research grants that would combine energy research manpower development and technology transfer extension focused on national and/or regional energy R&D problems.

8.1 Introduction

In previous chapters the Panel has recommended a number of ways to strengthen university participation and involvement in DOE's R&D programs. These programs generally are organized on a disciplinary basis, as in the ER Basic Energy Sciences Program, or on discrete technologies, such as light-water reactor development or biomass conversion, etc. However, most energy problems involve a variety of elements, including physical science, engineering, biological and social sciences, economics, environmental concerns, and institutional factors. In addition, energy problems often have significant regional, state, and local implications. The solution of many energy problems often requires either a multidisciplinary approach (where specialists from different disciplines pursue research in parallel on a common problem) or an interdisciplinary approach (where researchers from different disciplines work closely together on a common problem sharing their individual expertise).

8.2 Concerns and Comments

8.2.1 Current focus of DOE support

Typical of major universities is the availability of a broad range of disciplinary and subject area expertise among the faculty as well as facilities and instrumentation required for such research. Currently, however, university funding from DOE has been almost exclusively focused on support for discipline-oriented, basic energy research projects. There are relatively few examples of DOE university projects that combine a number of research tasks into one program. For the most part, such programs principally involve scientists in closely related disciplines and fields, such as corrosion research, combustion, etc. On the other hand, many of the national laboratories have large, ongoing research programs that involve teams of scientists and engineers from many different disciplines. The Panel believes it would be valuable to develop similar research programs in a number of universities for both mid- and long-term energy R&D and suggests the Department consider establishing a new university research program that would support multidisciplinary and interdisciplinary research and related activities on major energy R&D problems.

8.2.2 University outreach/extension capabilities

Another dimension of the university community currently unrecognized by DOE is the extensive outreach or extension capabilities

found in many universities. Most major universities, particularly those classified as land-grant institutions, have historically played important roles in the transfer of scientific and technical information to both general and specific audiences including industry and public agencies through a variety of formal and informal channels. The most visible and successful example of this is, of course, in agriculture. Energy use and conservation, as both a national and regional/state concern, might also benefit from this type of university expertise.

8.2.3 Programs of other Federal agencies

Programs supported by other Federal agencies would indicate a possibility of success for this type of effort for DOE. For example, the Environmental Protection Agency has supported on a *competitive basis* several large university-based interdisciplinary research efforts on both regional- and national-level environmental problems. Faculty at both the University of Illinois and Ohio State University have studied environmental problems related to energy development along the Ohio River Basin, and faculty at the University of Oklahoma carried out a major integrated scientific, technical, and policy-oriented research program on groundwater resources in the Rocky Mountain West. The NSF, beginning in the early 1970s and continuing today, has supported many problem-focused, multidisciplinary and interdisciplinary university research programs, including a major interdisciplinary effort on environmental research at the California Institute of Technology. As noted, the entire agricultural experiment station network and associated agricultural research programs at land-grant universities is another successful model of how universities can bring together teams of specialists to focus on one or more common problems with not only national but also significant regional and local implications.

8.2.4 State support for university energy-related research

The proposed program could also take advantage of and benefit from the substantial state support many universities receive for energy-related research. For example, the University of Hawaii is given by the state about $200,000 to $300,000 per year for energy research projects that are also supported by Federal and private sources. Louisiana State University received $900,000 in initial funding from the state for the development of a campus-wide energy research program. The close ties between the major universities in Michigan and the state government in energy R&D are described in a case study included in Volume II, Chapter 5. DOE, in general, has not fully recognized, or integrated its research with, the considerable interest in many states in university energy research. This suggested new program, incorporating national, regional, and state-based elements of a given energy R&D problem, could further stimulate state interest and support in energy research.

8.2.5 Summary

The Panel suggests that consideration of such a new university program (including research emphases, project selection, funding procedures, etc.) be an early agenda item for the proposed DOE-University Forum discussed in Chapter 7. However, the Panel in no way envisions a program initiative that is based solely on geographical considerations or that requires an entitlement or formula approach to the awarding of grants.

8.3 Findings and Recommendations

8.3.1 Findings and conclusions

- Some universities have substantial multidisciplinary and interdisciplinary research capabilities that can be focused on energy R&D problems of both a national and regional nature.
- Some universities have traditionally carried out significant technology transfer through such mechanisms as university extension programs, agricultural and engineering experimental stations, etc. These mechanisms may be appropriate for providing information services in conservation and renewable energy areas.
- Regionally-oriented research needs are not normally addressed by DOE programs.

- Many states have provided considerable funding for university energy R&D, but DOE, in general, has not taken advantage of this support.

8.3.2 Recommendations

1. The Department should consider the initiation of a new university research program incorporating multidisciplinary and interdisciplinary research, manpower development, and public outreach/extension focused on both national-level and regional-state R&D problems.
2. The concept of and policies/procedures for this proposed program should be discussed in the proposed DOE-University Forum.

9. CONCLUSION

It is essential to restate at this point the Department of Energy's overall policy regarding what the support of energy R&D should generally be, and that is to find and support the most qualified researchers and research groups to carry out DOE-sponsored research.

Within this context, as the Department proceeds to consider the various recommendations in this report regarding how to strengthen the Department's relationships with the university community, it is worth restating what it is that makes universities unique.

While universities are the prime performers of basic research in this country, they are also substantially involved in applied research. Universities are the source of all new scientists and engineers. University research and graduate training are interrelated and inseparable. These are the characteristics of universities that separate them from all other performers of energy R&D. It is essential that DOE managers recognize the special qualities of universities as institutions vis-a-vis the national laboratories and private industry.

The President's Science Advisor, Dr. George Keyworth II, summarized this as follows:

> As a group, American research universities are the best in the world, both in terms of producing the new knowledge that stimulates technology and in terms of producing the people who drive the innovative processes in society. . . . No other research institutions—federal laboratories, nonprofit organizations, or industrial laboratories—give so much return on investment in the long-term. No other institutions produce both knowledge and people.[1]

[1]*Science* **220**, June 10, 1983, pp. 1122-1125.

However, DOE must recognize that universities are not monolithic institutions. A university, like any other organization, is a collection of individuals. Unlike other organizations, universities are dominated by the need to provide an environment in which free intellectual inquiry and the transmission of knowledge can take place. Universities differ widely from one another in size, physical facilities, and research capabilities. There are large research-oriented universities, both public and private, where graduate research and education is the overriding interest. There are smaller colleges that are devoted to teaching, principally at the undergraduate level. Some universities are capable of carrying out major multidisciplinary and interdisciplinary research programs. Others are much more suited to the nurturing of individual scientists carrying out discipline-oriented research. Some universities have particular capabilities to address regional problems and concerns. DOE policies towards universities must recognize, encompass, utilize, and allow for this broad diversity.

To summarize, the Panel believes that the capabilities of universities as institutions devoted to advanced research and manpower development and of university scientists as individuals have, in general, not been fully recognized by or capitalized on by the Department in relation to the Department's needs. The Panel believes that this can be corrected in a relatively short time if the Department takes decisive action to resolve, *in priority fashion*, the issues and concerns discussed in this report.

ATTACHMENT A

DEPUTY SECRETARY'S CHARGE

Department of Energy
Washington, D.C. 20585

November 5, 1982

Mr. Louis H. Roddis, Jr.
Chairman, Energy Research
Advisory Board
110 Broad Street
Charleston, SC 29401

Dear Lou:

The Energy Research Advisory Board recently completed an excellent study of the Department's multiprogram laboratories. Your recommendations on ways to improve the effectiveness of these important institutions are being carefully and thoroughly considered.

National progress in fundamental research and other areas of science and engineering depends very substantially on the effectiveness of the Department's use of all available scientific and technical resources; laboratory, university and industry personnel. The Department currently provides about $300 million in direct support of university research, and about an equal amount in indirect support for activities at universities that contribute to our missions. It is essential to ensure that university research and manpower development activities are adequate, effective and consistent with the Department's missions and the needs of our energy R&D programs.

I request, therefore, that ERAB examine the broad issue of the roles and missions of universities' research and development and specifically address the effectiveness of the Department's policies toward and working relationships with the academic community. Within this framework, the Board should explore, among others, the following questions:

- Is the Department effectively utilizing the general capabilities of the university community in both fundamental and energy research?
- Is the Department effectively utilizing universities, vis-a-vis laboratory and private sector groups, in energy research and technology development programs?
- What responsibilities and mechanisms are appropriate for the Department in professional level manpower development including, but not limited to, support for graduate students, postdoctoral researchers, and younger faculty members?
- What current factors, actual or perceived, foster or impede good working relationships between the Department and the academic community.

- In what ways, if any, could the Department improve the effectiveness of the working relationships between the DOE laboratories and the universities including, for example, the planning and conduct of joint research programs?

- What changes, if any, should the Department make in order to provide the most effective support of university-based energy research?

These are only a sample of the obviously complex issues the Board may wish to address. You can be assured of the full cooperation and assistance of the Department as you plan and carry out this study. The schedule will, of course, be established by the Board in relation to other priorities. However, I would appreciate a final report by August 1983.

By copy of this letter, I am requesting the Director of the Office of Energy Research, the Assistant Secretaries and the Operations Office Managers to give you their fullest cooperation and support. Staff assistance for this study will be provided by the Office of Energy Research.

I look forward to discussing this subject with you and receiving your report and recommendation.

Sincerely,

W. Kenneth Davis
Deputy Secretary

ATTACHMENT B

SUMMARY OF DOE SUPPORT FOR UNIVERSITY ENERGY R&D

ATTACHMENT B

SUMMARY OF DOE SUPPORT FOR UNIVERSITY ENERGY R&D

Direct Funding of University R&D

The Department of Energy (DOE) is the fourth largest federal sponsor of university R&D, directly providing an estimated $317 million for university R&D in 1983. Within the DOE, the Office of Energy Research (ER) is the largest sponsor of university R&D, providing 75% of the total DOE funds for university research in FY 1983. ER administers long-range research programs, oversees the DOE national laboratories and other major performers of research, and helps to ensure adequate future manpower supplies. The office itself was specifically authorized and created as a result of a House floor amendment to the original DOE organization act in 1977. This amendment was developed primarily in response to concerns in the university research community over the lack of a central organization in the new Department responsible for long-range research.

Four major programs in ER provide the principal university support: Basic Energy Sciences, Biological and Environmental Research, High-Energy/Nuclear Physics, and Fusion.

The Basic Energy Sciences Program (BES) is the primary supporter of long-range, basic energy-related research. BES directly provided about $55 million in current dollars (25% of its budget) to university R&D in 1981 and 1982. BES programs support approximately 1200 individual research projects—each selected on the basis of scientific merit, relevance to BES long-range goals, and contribution to energy R&D. Although a large proportion of BES funds goes to the national laboratories (about 68% in 1983), a significant portion of the laboratory funds indirectly supports university R&D (this is discussed further in a subsequent section).

The Office of Health and Environmental Research (OHER) supports fundamental and applied research, through the Biological and Environment Research Program, to investigate the long-term health and ecological effects associated with energy technology development. The 1981 and 1982 university funding levels from OHER were $48 million and $33 million in current dollars, respectively. These figures represent approximately 20% of the total OHER budget. About 240 individual university research projects were supported in FY 1982. Funding is also provided for seven on-campus research laboratories that carry out large, multidisciplinary research programs. Both BES and OHER rely on unsolicited research proposals for support for university research. Tables B.1 and B.2 summarize funding provided by BES and OHER to universities, national laboratories, and other performers.

The High-Energy/Nuclear Physics Programs provided $67 million and $78 million in current dollars to university R&D in 1981 and 1982, respectively. However, a much higher level of university support is provided by the High-Energy Physics Program through the use of large particle accelerators and experimental facilities at the Stanford Linear Accelerator, Fermilab, and Brookhaven National Laboratory. Overall, between two-thirds and three-fourths of the high-energy physics research at the laboratories is performed by university research teams and can be considered as indirect university support. The High-Energy Physics Program included direct funding to provide partial support for about 180 research groups at approximately 90 universities. The

Table B.1. Comparison of university and national laboratory funding by major programs FY 1983 (estimate)

(budget activity in thousands of dollars)

Basic Energy Sciences Program	National laboratories[a]	Universities	Other	Total
Nuclear Sciences	21,628	7,880	1,136	30,644

[a]Laboratory funding includes significant support for university scientists who use laboratory facilities for research.

Source: Office of Energy Research, Department of Energy.

Nuclear Physics Program provided 25% of its total budget for university research programs and accelerator laboratories at Duke University, the Massachusetts Institute of Technology, Texas A&M University, the University of Washington, and Yale University. The Program directly supports 75 university user groups who perform their research at the DOE national facilities or at their home universities.

Other university-related programs supported by ER include the University Reactor Fuel Assistance Program (which provides fuel for university nuclear reactors), the Manpower Assessment Program (which carries out energy-related manpower supply/demand studies), and the Prefreshman Engineering Program (which is directed at providing instructional assistance to women and minority students in high school who are interested in pursuing engineering at the college level).

The Fusion Energy Program directly sponsored $32 million in current dollars for university R&D in both 1981 and 1982. The goal of this program is to develop the technology for

safe, economic, and environmentally acceptable use of fusion power for electrical generation and to develop other applications for the use of the fusion process. Funding is provided to individual university researchers and to the large university-based facilities at Princeton and the Massachusetts Institute of Technology. The Program typically supports 80 university projects including the large university research laboratory project. Most of the awards are based on unsolicited proposals that have been reviewed for their merit.

The energy technology program offices of DOE (Fossil Energy, Conservation and Renewable Resources, etc.) provide support for the further development of their respective energy technology (e.g., predemonstration) programs. The projects supported by these programs are fewer in number, larger in size, and more applied in scope than those supported by ER. Support by the technology program offices for university research is generally based on competitive solicitations. Recent budget reductions in these programs are reflected in the university funding levels for 1981 and 1982: Fossil Energy—$45 million and $20 million, and Nuclear Energy and Defense—$17 million and $10 million, respectively. Regarding the allocation of funds by the various technology offices to the national laboratories, the Fossil and Nuclear programs provided about 10% and 75%, respectively, in FY 1983 to the national laboratories or other operating contractors.

Manpower development and training

The AEC/ERDA/DOE have not had a direct statutory role in manpower development. However, early in the AEC program it was determined that the agency had a special responsibility to encourage young people to enter nuclear science and related energy fields for future careers. Therefore, in 1948 the AEC began providing support for graduate traineeships and fellowships in accordance with its mission. The ERDA and DOE have adopted similar approaches toward manpower development, even though actual funding mechanisms for the programs have changed. Within DOE, ER has been assigned the principal task of ensuring adequate supplies of manpower to meet the nation's needs.

DOE supports approximately 5000 graduate students and additional numbers of faculty per year through the various research and training programs offered at the national laboratories. These programs include the University-Laboratory Cooperative Program, which supports approximately 2000 faculty and students per year. These programs benefit both university faculty and students by providing invaluable training and research opportunities and benefit laboratory staff by providing invaluable interactions. In presentations before the Panel, representatives of the University-Laboratory Cooperative Program contractors (Argonne National Laboratory, Associated Western Universities, Brookhaven National Laboratory, and Oak Ridge Associated Universities) noted that the various programs have both the capacity and the desire to host at least twice the number of participants, if additional funding were available.

Strong emphasis is also placed by DOE on the important adjunct roles played by the national laboratories in education and manpower development. Thus, DOE and the laboratories offer several programs to enhance university research and manpower development efforts. One such program is the University of Tennessee/Oak Ridge National Laboratory Graduate School of Biomedical Sciences. The school is nationally recognized and offers training at the laboratory and job placement upon completion of the degree. One effort common to all the laboratories is that laboratory staff serve as adjunct faculty to various universities and/or participate in lecture/seminar series at universities. Several new university-related programs are now offered through the national laboratories, including joint programs with minority colleges, distinguished visitor and distinguished scientist programs, and laboratory fellowship programs. DOE has also initiated efforts through the laboratories to enhance high school education in science and mathematics. The DOE funding for all of these efforts is approximately $5 million per year. It should be noted that the DOE funding for these programs has also not been tabulated into the $200 million indirect support as men-

tioned above. Therefore, the total indirect DOE funding to universities is probably at least three-fourths of the direct DOE funding ($273 million in current dollars) for 1982.

Facilities and instrumentation support

Historically, support of specialized university research facilities and instrumentation (nuclear research and training reactors, particle accelerators, etc.) has been an important effort in the Department. Between 1970 and 1980, DOE support of R&D Plant and Instruction Facilities increased from $13.8 million to $21.5 million, representing a 56% increase. Again, the DOE provides additional significant indirect support for facilities and instrumentation at the national laboratories for university staff use. The Department also has a Used Equipment Program, which provides excess research equipment to the academic community (although the program is limited to instrumentation valued at between $300 and $10,000). Finally, a new program is being developed as part of an interagency effort coordinated by NSF. The DOE FY 1984 budget includes $4 million for university research instrumentation support that will be used to purchase equipment ranging in cost from about $100,000 to about $800,000.

Indirect Funding Through the DOE National Laboratories

The Department provides additional support to university R&D through its contractors by means of subcontracts and by providing access to user facilities at the DOE national laboratories [including the nine multiprogram laboratories (MPLs) and the large accelerators]. These DOE activities represent significant but "hidden" support for university research; this support, which has grown rapidly, totaled over $200 million in FY 1982. In fact, university subcontracting through the MPLs alone totaled $37.9 million in FY 1982. The amount of subcontracting to universities varies widely among the various MPLs from 0.7% to 11% of their DOE (nondefense) operating budgets. In addition to subcontracts, large numbers of university faculty members receive consulting subcontracts for research activities at the national laboratories; however, all the funds for these consulting subcontracts are not included in the above total.

DOE user facility support totaled $70.3 million in FY 1982; this figure is based on estimates of the proportion of the total facility operating budget that actually went to support university research. The DOE offers these programs because of the national need for research conducted at these expensive facilities.

Most of the DOE user facilities are made available at no or minimal cost to the user, as long as the research is not proprietary. For example, there is no charge for use of seven of Argonne's eleven major user facilities. However, Argonne received 120 proposals for experimental work on the Intense Pulsed Neutron Source in FY 1982: this is far more work than could possibly be accommodated even if the device were run 24 hours per day for an entire year. The other laboratories report similar experiences.

Overall the major user facilities funded by BES average 57% use by university staff. This does not include the proportion of Ames and Lawrence Berkeley Laboratory staff who have joint faculty appointments with their host universities. The new facilities such as Brookhaven's National Synchrotron Light Source and Sandia's Combustion Research Center will become increasingly important to university researchers. In recent years the Department has placed strong emphasis on the development and operation of new user facilities at the laboratories.

Finally, additional indirect funding is provided through the national laboratories and DOE contractors for manpower development and training. However, the overall funding levels for these programs is not known, and as a result, this type of support to universities is not included in the above-mentioned $200 million that DOE provides indirectly to universities.

AGENDAS FOR PANEL MEETINGS

University Programs Panel
Energy Research Advisory Board
Agenda

20 January 1983
Forrestal Building
Room 8E-089

9:00	Convene Introduction of Members and Staff Opening Remarks	Ivan Bennett Chairman
9:15	Current Federal Policies/Programs Regarding University R&D University Research and Development	George Keyworth II Director, Office of Science and Technology Policy Executive Office of the President
10:00	Review of DOE University R&D Programs	Alvin Trivelpiece Director, Office of Energy Research
11:00	Administrative Items	Mary Gant Joan Snodderly ERAB Staff
11:15	Discussion of Issues to Be Considered in Reports	Ivan Bennett
12:00	Lunch	
1:15	Continued Discussion of Issues	Ivan Bennett
2:00	Status Report and Possible Studies	Colin West Oak Ridge National Laboratory
2:30	Discussion of Future Meeting Schedule and Agenda	Ivan Bennett
2:45	Break	
3:00	Review of Department of Defense University R&D Programs	Leo Young Director Research and Technical Information, DOD
3:30	Review of NASA University R&D Programs	Hans Mark Deputy Administrator, NASA
5:00	Adjourn	

62

University Programs Panel
Energy Research Advisory Board
Agenda

February 14, 1983
Forrestal Building
Room 8E-089

9:00	Convene Opening Remarks and Administrative Items	Ivan Bennett Chairman
9:30	Trends in Manpower, Federal and Industrial Funding for R&D in Universities	Charles Falk Director Science Resource Studies National Science Foundation
10:30	Energy Research University Programs	James Kane Deputy Director Energy Research
11:15	Nuclear Energy University Programs	Tom Dillon Deputy Assistant Secretary Nuclear Energy
11:45	Fossil Energy University Programs	Bob Roberts Senior Scientific and Technical Advisor Office of Fossil Energy
12:15	Lunch	
1:15	DOE University Procurement Policies and Procedures	Hilary Rauch Director Procurement and Assistance Management
2:00	Status Report on Studies	Colin West Oak Ridge National Laboratory
2:30	Adjourn	

63

University Programs Panel
Energy Research Advisory Board
Agenda

21 March 1983
Forrestal Building
Room 8E-089

9:00	Convene Opening Remarks and Administrative Items	Ivan Bennett Chairman
9:10	Conservation University Programs	Howard Coleman, Principal Deputy Assistant Secretary for Conservation and Renewable Energy
9:35	Preliminary Report on Survey of University Associations, Officials and Scientists	Colin West Oak Ridge National Laboratory
10:05	Break	
10:15	Presentations by Representatives from Universities on DOE Programs, Policies, and Procedures	George Dummer, Director of Sponsored Programs, MIT Robert Marston, President University of Florida T. A. Tombrello, Department of Physics, California Institute of Technology David Menzel, Director Skidaway Institute of Oceanography, University of Georgia Joseph E. Lannutti Associate Vice President Academic Affairs, Florida State University
11:15	Discussion with University Representatives	
12:00	Lunch	
1:00	Renewable Energy University Programs	Robert San Martin, Deputy Assistant Secretary for Renewable Energy
1:30	National Laboratory Programs and Policies Relating to Universities	Herman Postma, Director Oak Ridge National Laboratory Douglas Olesen, Director Pacific Northwest Laboratory
2:30	Discussion of Panel Report	Panel Members
5:00	Adjourn

ATTACHMENT E

DRAFT DOE POLICY STATEMENT OF DOE-UNIVERSITY RELATIONSHIPS

ATTACHMENT E

DRAFT DOE POLICY STATEMENT OF DOE-UNIVERSITY RELATIONSHIPS

Subject: Basic Policy for DOE-University Relationships

Purpose

This memorandum provides policy guidance with regard to relationships between the Department of Energy and universities and colleges participating in Department-supported research and related activities.

Definition

In this memorandum, *university* is used as a generic term covering all nonprofit institutions of higher education and educational nonprofit organizations that are directly affiliated with such institutions. The term *research* is principally defined as that research necessary to expand the energy technology base and includes both general scientific research and basic applied research and exploratory development.

Background

Universities are unique national resources responsible for conducting long-range research, educating students, and providing technical assistance to external groups through public service and outreach. Universities have traditionally played important roles in major national programs such as national defense, agriculture, health and human services, and the aerospace program and in general science and technology development. University scientists and engineers have also made significant contributions through research to the development of new, more effective energy technologies and through this process have provided the necessary education for new scientists and engineers needed for both current and future energy programs.

University Participation in Department Programs

The Department bases its research support policy on the criterion of excellence, regardless of the location and type of performer. The competitive process provides the highest assurance that the best research will be supported. University participation in Departmental research should not be based on "set asides" or otherwise sheltered funding except in unusual circumstances but rather on identification of those university researchers who are the "best performers," recognizing contributions to the education of new scientists and engineers as one important dimension of performance. It is within this policy context that the Department seeks to encourage and support the involvement of university scientists and students, wherever appropriate, in each research and technology development program. To a significant degree, this support constitutes a necessary national investment in sustaining the quality and quantity of well-trained scientific and engineering personnel who, in the future, will be required to meet the nation's needs.

In pursuing these policies, taking into account the special nature and capabilities of the universities, the Department must follow clear criteria. In particular, principal emphasis should be on engaging universities and university scientists in advanced, long-term research that strengthens the technology base for all energy-related areas and that includes students as active partners and participants. In addi-

tion, it is important that the Department foster close cooperation in research and education between universities and industry and between the national laboratories and universities—viewing all three elements as a coherent system to which each contributes and from which each derives benefits. At the same time, it is obvious that each critical element, whether a university, a national laboratory, or an industrial performer, operates in a distinct and differing environment from the others. Hence, Departmental managers are expected to recognize these differences and apply appropriate management and administrative systems and techniques that are compatible with the distinctive needs and circumstances of each major element.

Policy

To accomplish the above, it is the intent and policy of the Department to

1. involve university scientists in Departmental energy research and development programs with the expectation that they will conduct a significant fraction of the advanced, longer-term technology base research required by individual agency programs;
2. avoid the use of special funding set-asides for university support except in unusual circumstances;
3. solicit and incorporate the advice of university scientists and engineers, either as individuals or through established advisory groups or professional associations, in the planning and execution of energy research and technology development programs;
4. recognize the educational impact and benefits of advanced research by encouraging and providing support for the participation of students in all appropriate Department-sponsored university projects;
5. encourage university researchers to show independence and creativity in their advanced research, including, where appropriate, the preparation and submission of multidisciplinary, cross-programmatic research proposals, subject to periodic peer and program evaluation;
6. encourage interaction and collaboration in energy research among universities and industry, the national laboratories and the Energy Technology Centers, including consideration of and, as appropriate, support for joint research projects;
7. provide increased opportunities for faculty and students in traditionally minority universities, including the Historically Black Colleges and Universities, to participate in Department-sponsored research, both directly and through the national laboratories;
8. expand opportunities for university researchers to use the special and unique facilities and equipment in the multiprogram national laboratories and energy technology centers, whose directors are responsible for ensuring appropriate access to such facilities for university researchers;
9. ensure that the execution and administration of university research grants and contracts are in conformity among all the cognizant field procurement offices; and
10. conduct the Department's overall relationships with the university community in a manner that reflects concern and understanding for the special role of universities in research and education and avoids imposition of burdensome administrative requirements not suited to a university research environment.

Policy Guidelines

The following guidelines are established to ensure that the Department's university programs conform to the spirit of the policies stated above:

1. In addition to responding to competitive solicitations, university scientists should be encouraged to submit unsolicited research proposals to all Departmental programs. Announcements outlining programmatic research interests and needs should be widely distributed, written in a clear and concise form, and require the least burdensome type of response. Notices of Program Interests are particularly appropriate. Efforts should also be made by program staff to review preliminary proposals or other preproposal information from university scientists. Such efforts will enable these researchers to gain a more comprehensive understanding of the

objectives of the Department's energy research and development programs and aid them in focusing their research on the most suitable topics and problems.

2. Department-sponsored research projects should be generally compatible with the interests and capabilities of universities and should normally avoid support for short-term, subprofessional types of work that do not directly or significantly contribute to the university's educational mission.
3. Wherever possible, reasonable continuity of university research projects should be maintained. This requires programmatic and administrative attention to timely award renewals and the use, where appropriate, of multiyear awards to help minimize adverse and burdensome effects on faculty, students, and the institution. Abrupt changes in the funding and monitoring of ongoing university research projects should be avoided. Particular care should be taken to ensure that adequate funding stability is provided to university research projects involving graduate students.
4. Reporting and administrative requirements on university research projects should be held to the minimum consistent with the Department's financial and program management oversight responsibilities.

Responsibilities

1. The responsibilities for implementing the above policies and for strengthening current and developing new university research programs is delegated to the appropriate Program Assistant Secretaries and the Director of Energy Research with overall coordination provided by the Under Secretary.
2. To evaluate the effectiveness of the Department's support of university research, the Under Secretary, with the assistance of the Director of Energy Research and the Program Assistant Secretaries, will prepare for the Secretary an annual report describing the extent and types of university involvement in Departmental programs.
3. The Assistant Secretary for Management and Administration is responsible for ensuring that administrative requirements, including procurement/assistance requirements, on university research projects are applied consistently throughout the Department and at the minimum level necessary to fulfill Departmental financial and award oversight procedures.

The Department of Energy Multiprogram Laboratories

Prepared by the Multiprogram Laboratory Panel

September 1982

A Report of the
Energy Research Advisory Board
to the
United States Department of Energy
Washington, D.C. 20585

Department of Energy
Washington, D.C. 20585

ENERGY RESEARCH ADVISORY BOARD
September 16, 1982

Honorable W. Kenneth Davis
Deputy Secretary of Energy
1000 Independence Avenue, S.W.
Washington, D.C. 20585

Dear Ken:

I am pleased to forward the final Report of the Multiprogram Laboratory Panel of the Energy Research Advisory Board. This report, approved unanimously by the ERAB on September 10, 1982, was prepared in response to your request on September 29, 1981, to undertake a comprehensive study that will help shape the future of the Department's multiprogram laboratories.

Among the several findings and recommendations of this report is a greater need for stability and continuity in policy and purpose in managing and funding the Laboratories. This need arises from a decade of major shifts, the result of both Congressional actions and shifts in Administration policies. Obviously such changes are fundamental to our system of government and are not likely to be avoided. Some of the major impacts on the multiprogram national laboratories might have been reduced if there had been a single, stable, top-level office concerned only with the laboratories as long-term assets, physical and personnel. The present situation is in part the result of overfragmentation of the long-term programmatic decision process. A major recommendation aims at establishing such a functional office in the Office of the Under Secretary. In addition, the Board recommends that the Department urge the Office of Management and Budget to support rolling two-year Congressional appropriations for research and development with carry-over funding to stabilize further Department and laboratory planning and program execution.

The Board is in full agreement that the multiprogram laboratories are an impressive research and development asset. The Board recommendations, listed in the Executive Summary, are designed to suggest to the Department means by which the laboratories can be utilized even more effectively.

Sincerely,

Louis H. Roddis, Jr.
Chairman
Energy Research Advisory Board

Enclosure

Department of Energy
Washington, D.C. 20585

ENERGY RESEARCH ADVISORY BOARD

August 31, 1982

Mr. Louis H. Roddis, Chairman
Energy Research Advisory Board
110 Broad Street
Charleston, South Carolina 29401

Dear Lou:

I am pleased to submit the Final Report of the Multiprogram Laboratory Panel to the Energy Research Advisory Board for consideration at its meeting on September 9-10. Since the White House Science Council Federal Laboratory Review Panel has asked ERAB to brief it in mid-September on the results of the laboratory study, action by ERAB at the September 9 meeting would be most timely.

The Final Report completes the Panel's work in connection with the Deputy Secretary of Energy's request to ERAB to provide a comprehensive study to aid the Department in planning for the future of the multiprogram laboratories. There is general agreement among Panel members on the findings and recommendations.

The Panel very much aporeciates the cooperation of the laboratories, operations offices, and Headquarters in this effort. To facilitate ERAB's review, I am sending the report to all Board members by copy of this letter.

Sincerely,

Ivan

ABSTRACT

The Final Report of the Multiprogram Laboratory Panel of the Energy Research Advisory Board responds to the Department of Energy's request for "a comprehensive study that will help shape the future of the Department's multiprogram laboratories." The Panel assessed, in energy-related areas, the appropriate roles and missions of the laboratories vis-à-vis industry and universities, the scientific and technological capabilities of the laboratories, the Department's policies and procedures with respect to the laboratories and the effectiveness of the Department's use of the laboratories.

The laboratory complex constitutes an impressive national research and development asset. However, the industry and university research establishments often carry out comparable work, usually with differing goals, objectives, and institutional settings. The issue at hand is how to make use of all of these resources for the benefit of the country as a whole.

The Panel recommends the following major roles and missions for the laboratories:

- Perform the Department's "national trust" fundamental research missions in the physical sciences, including high energy and nuclear physics, and the radiobiological sciences including nuclear medicine;
- Sustain scientific staff core capabilities and specialized research facilities for laboratory research purposes and for use by other Federal agencies and the private sector;
- Perform independent scientific and technical assessment or verification studies required by the Department; and
- Perform generic research and development where it is judged to be in the public interest or where for economic or technical reasons industry does not choose to support it.

The Panel finds that organizational efficiencies if implemented by the Department could contribute toward optimal performance of the laboratories. The Panel recommends that a high level official, such as a Deputy Under Secretary, be appointed to serve as Chief Laboratory Executive with authority to help determine and defend the research and development budget, to allocate resources, to decide where work is to be done, and to assess periodically laboratory performance. Rolling two-year appropriations by Congress for research and development are recommended as a stabilizing measure. The Panel also recommends that laboratory directors be given substantially more flexibility to deploy resources and to initiate or adapt programs within broad guidelines provided by the Department.

The Panel recommends the following actions to increase the usefulness of the laboratories and to promote technology transfer to the private sector:

- Establish user groups for all major mission programs and facilities to ensure greater relevance for Department and laboratory efforts.
- Allow the laboratories to do more reimbursable work for others (other Federal agencies, state and local governments, and industry) by relaxing constraints on such work.
- Implement vigorously the recently liberalized patent policy.
- Permit and encourage joint ventures with industry.
- Expand laboratory/university cooperation in the training of scientists and engineers at laboratory facilities.

Finally, the Panel finds that some of the multiprogram laboratories are currently funded at close to minimum levels for maintaining their present capabilities. In the event of further budgetary reductions, some measures, such as narrowing laboratory missions or directing additional work to them in lieu of establishing new laboratories, are suggested for preserving as much as possible of the capabilities of the laboratory complex.

I. EXECUTIVE SUMMARY

In specific terms, the Deputy Secretary of Energy charged the Energy Research Advisory Board with assessing, in energy-related areas, the appropriate roles and missions of the laboratories vis-à-vis industry and universities, the scientific and technological capabilities of the laboratories, the Department's policies and procedures with respect to the laboratories and the effectiveness of the Department's use of the laboratories. The recommendations of this Executive Summary and the body of the Report respond to these specific charges.

In a broader context, the Deputy Secretary requested "... a comprehensive study that will help shape the future of the Department's multiprogram laboratories." In responding to this request the Multiprogram Laboratory Panel found it appropriate, and indeed mandatory, to consider a broader laboratory role in innovation and productivity in the national economic interest. The Panel concluded in this regard that the present management direction and practices respecting the laboratories, developed over time, are not consistent with their long-range future well-being and, further, that these arrangements deny to the Nation the full benefits of this national research and development asset.

A. The appropriate roles and missions of the laboratories vis-à-vis universities and industry (see pp. 13-15).

1. Findings

- The multiprogram national laboratory complex constitutes an impressive national research and development asset. Moreover, it possesses capabilities for the performance of large-scale, long-term, high-risk, multidisciplinary research and development; however, these characteristics in and of themselves do not uniquely define appropriate roles and missions for the national laboratory complex. The industry and university research establishments are capable of and often carry out work comparable to much of that performed by the national laboratories, albeit often with differing goals, objectives, and institutional settings. The issue at hand is how to make the best use of the existing research and development assets of the multiprogram laboratories in the context of the national scientific and technical enterprise.
- Current Administration policy calls for increased reliance upon the private sector for technological advancements but recognizes an appropriate Federal role in supporting long-range, high-risk, potentially high-payoff research and development of national interest beyond that which can be expected from the private sector. The Panel concludes that there exist areas of research and development that require the complementary capabilities of the university, industrial, and laboratory sectors.

2. Recommendations

In energy-related areas, the Panel recommends the following functions as appropriate for performance by the national laboratory complex, subject to university and industry participation as noted.

a. Direct Functions

- Carry out core elements of the Department's traditional "national trust" fundamental research missions in the physical sciences, including high energy and nuclear physics, and the radiobiological sciences, including nuclear medicine; in so doing,
  - perform research utilizing their unique capital intensive research facilities to ensure that the capabilities of the facilities and scientific staff evolve appropriately to meet the needs of university, industrial, and other Federal research communities.
  - exercise stewardship of these facilities and provide associated technical expertise to enable their efficient use by these communities.
- Perform research and development on the health, safety, and environmental externalities incident to promising energy technologies under development (not necessarily limited to those enjoying government funding) whenever high scientific competence or specialized facilities are available at the laboratories or when performance of such work by industry or, where relevant, universities would pose an apparent or actual conflict of interest.

- Perform generic energy research and development where it is judged to be in the public interest or where for economic or technical reasons industry does not choose to support it. Government funding may provide support for either universities, industry, or the national laboratories, consistent with:
  - i) Department utilization of the best available performer for the given task
  - ii) Cooperation with intended users of the technology in determining applications oriented work to be performed in the laboratories
  - iii) Industry access to the facilities and staff of government laboratories for research and development funded privately, or with government funds, under appropriate policy guidance.

b. Support Functions

- As requested, and in conformance with explicit policy guidelines and budgets established by the Department, act as agents for the Department in exercising broad technical management responsibilities for complex packages of multilaboratory and/or subcontracted research and development work.
- In accordance with applicable Department policy, make the special capabilities and expertise of the laboratories available for technical assistance and reimbursable research and development to other Federal agencies; state and local governments; and regional entities, universities, and industry.
- Within their areas of capability and expertise, contribute toward the education and training of scientists and engineers by providing opportunities for this purpose at the laboratories to university faculty and students, industrial professionals, and, in accordance with national policy, foreign nationals.
- Assist the Department in the discharge of its overall resposibilities by:
  - providing technical counsel to the Department on national research and development policies and future directions
  - acting as systems engineers, advisors, and evaluators for the Department in areas where such involvements by others would constitute an apparent or actual conflict of interest
  - providing a fast start-up or multidisciplinary approach not otherwise readily available to meet quickly an urgent or emergency need for research and development, technical expertise or timely and reliable data of a critical nature
  - supporting fulfillment of international agreements.

B. The scientific and technological capabilities of the laboratories (see pp. 17-19).

1. Findings

- Overall, the Panel finds the scientific and technological capabilities of the laboratories impressive, but DOE organizational inefficiencies and funding policies are obstacles to their full realization.
- The Panel is uniformly impressed with the qualities and resourcefulness of laboratory leadership.
- The scientific and technical resources of the laboratories, including their physical facilities, cannot be utilized effectively under prolonged budgetary uncertainty and the pressure of repetitive crash readjustments in program funding.
- Layering and fractionation of managerial and research and development responsibilities in DOE require the laboratories to interact with DOE on an excessive number of horizontal and vertical levels and with heavy reliance on negotiation. The absence of a coordination and resolution officer with full authority at the Headquarters level giving attention and support to the laboratory directors results in inefficient utilization of laboratory scientific and technical capabilities.

2. Recommendations

- Urge the Office of Management and Budget to support rolling two-year appropriations by Congress for research and development with carry over funding to stabilize Department and laboratory planning and program execution.
- Designate a high level official, such as a Deputy Undersecretary, whose sole function is to be the Chief Laboratory Executive with authority to help determine and defend the research and development budget; to allocate resources; to decide where work is to be done; and to assess laboratory scientific, technical, and managerial performance.
- Consistent with the foregoing, modify the roles of the operations offices with respect to the laboratories to focus on management of the contracts with the laboratory operating contractors and to de-emphasize their function as policy and programmatic intermediaries between Headquarters and the laboratories.
- Arrange for the laboratory directors to have substantially more flexibility, within overall budgets and broad program guidelines, to reprogram assign-

ed laboratory resources and to initiate or adapt programs in accordance with research and development opportunities. This reprogramming authority should be no less than 5% or more than 10% subject to the satisfactory completion of the original assigned program activity. If additional Congressional authorization for this reprogramming is needed, the Department should seek it.

C. The Department's policies and procedures with respect to the laboratories. (see pp. 21-23).

1. Findings

- The laboratories have become grossly overburdened with detailed reporting and other paperwork requirements, the utility of which frequently is not apparent and which unnecessarily divert resources from their research and development missions.
- The Department's laboratory Institutional Planning Process is proving itself valuable, both to DOE Headquarters and the laboratories, although care needs to be taken that it produces a workable plan and not a strait jacket.
- The Department's approach toward appraising laboratory performance has been somewhat lacking in systemization, codification, and management follow-up. The Panel is pleased to note that the Department is in the process of rectifying this situation.
- The Department's restrictions on laboratory work for others, particularly industry, are unnecessarily constraining. Among other things, such restrictions frustrate technology transfer efforts.
- The Department's patent policy, particularly in connection with laboratory work for others, has been among the salient barriers to cooperative relationships with industry and to effective technology transfer. The Panel notes with approval that the Department recently has taken steps to liberalize its policy in this area.

2. Recommendations

- Utilize the services of an outside audit contractor familiar with both Government and industry practices to conduct a thorough audit of paperwork requirements in the Headquarters/operations offices/laboratory chain of command.
- Strengthen laboratory Institutional Plans as long-range strategic planning documents, as components of the Department's planning process, and as vehicles for new initiative proposals; de-emphasize their use as constraining budget documents.
- To supplement internal appraisals of laboratory performance, the Department should convene panels from recognized scientific bodies, such as the National Academies of Science and Engineering, to conduct periodic (at intervals not greater than five years) technical audits of laboratory programs in connection with approved institutional plans.
- While maintaining priority status for essential Department missions, allow the laboratories to do more reimbursable work for others (other Federal agencies, state and local governments, and industry) by relaxing constraints on such work.
- Undertake a well-planned education program among Headquarters, operations office, and laboratory staff on the recently liberalized patent policy to ensure that it will be vigorously implemented. In parallel, ensure that the private sector understands the new policy.

D. The effectiveness of the Department's use of the laboratories in meeting its energy objectives (see pp. 25-27).

1. Findings

- The Panel finds that the Department has been conservative in envisioning, not to mention implementing, policies by which the laboratories could be more effectively utilized. This conservatism has resulted in a lesser contribution by the laboratories toward meeting the Department's energy objectives than could otherwise be achieved.
- Contrary to past practices, the expertise of laboratory staff and directorate are not being utilized in establishing Department policy and directions for research and development.
- While laudable in principle, the Department's policy of assigning lead missions to the laboratories has been, with few exceptions, generally ineffective because of excessive fractionation of mission assignments, inadequate delegation of authority to the laboratories, and seeming lack of commitment to the policy by DOE management.
- Under present budgetary constraints a number of the specialized research facilities at the laboratories are being operated far below capacity.
- While use of the laboratories for contributing toward training scientists and engineers to meet the Nation's needs has grown in recent years, this use could increase.
- Research and development program planning does not consider adequately end-user views.
- Institutional and doctrinal barriers toward greater laboratory/industry cooperation continue to inhibit achievement of the Department's energy objectives in general and technology transfer efforts in particular.

2. Recommendations

- Establish a consultant group composed of all the laboratory directors to utilize more effectively laboratory resources in establishing the Department's research and development policy and directions.
- Implement vigorously the assignment of lead missions to the laboratories, defining these in terms of major applied programmatic missions, and provide for significantly greater laboratory discretion in allocation of resources (within overall Headquarters established budgets for the mission area) and in the selection of performers.
- In setting research priorities, give special weight to making optimal productive use of sophisticated equipment and facilities.
- Establish user groups reporting to the Department, similar to the High Energy Physics Advisory Panel and the Nuclear Science Advisory Committee, for all of the Department's major mission programs and facilities. These could be established independently for each program function or under the umbrella of an overall advisory group.
- Continue to support laboratory/university cooperation in the training of scientists and engineers through on-site participation by faculty and students in laboratory programs, term appointments, fellowships, etc.
- Permit and encourage joint ventures in selected projects with industry, including test and pilot demonstration (located at the laboratories or industrial sites) in order to test economic feasibility and to shorten the time lag for technology transfer.
- In areas of special laboratory expertise and capabilities, allow and encourage the laboratories to work more closely with industry by such means as responding to requests for proposals from industry cooperative groups (e.g., American Society of Heating, Refrigeration and Air-Conditioning Engineers; Electric Power Research Institute; and Gas Research Institute) and to work in partnership with industry in meeting technical needs of Federal agencies, as well as working directly for industry in connection with Federal agency requests for proposals.
- Permit each laboratory to use 1% to 2% of its capital and operating budget for independent research and development at the discretion of the laboratory director in order to enrich their research capabilities.
- Through a deliberate review and study by both the Department and the laboratories, identify institutional and doctrinal barriers to effective technology transfer and implement further actions to ameliorate these.

E. Alternative strategies for making best use of the laboratories in a contrained budgetary environment (see p. 27).

1. Findings

- Some of the laboratories are currently being funded at levels close to the minimum consistent with maintaining their present competence and vitality.
- In view of their current broader responsibilities, any further funding reductions that would reduce laboratory staffing below the levels of the mid-1970's would demand that a number of measures, some drastic, be considered to preserve as much as possible the scientific and technical assets of the laboratory complex.

2. Recommendations

Certain measures that would help stabilize the laboratory complex in the event of further budgetary reductions have validity in their own right as contributors toward more effective use of the laboratories. These measures, which have been addressed earlier, relate to the lead mission policy and the freeing of the laboratories to do much more work for others. Additional measures recommended for consideration if necessary include:

- Transferring appropriate DOE-sponsored work now performed by other Federal agencies and directing additional work into the laboratories by assigning to them those new tasks for which new laboratories might otherwise be established.
- Narrowing the missions of the laboratories to correspond to the resources available.
- Closing particular laboratories or merging one or more of them with other DOE laboratories or even with other appropriate institutions outside the Department.

II. INTRODUCTION

This Final Report responds to a request of September 29, 1981, from the Deputy Secretary of Energy (Attachment A) that the Energy Research Advisory Board (the Board) undertake "... a comprehensive study that will help shape the future of the Department's multiprogram laboratories." Specifically, the Deputy Secretary requested the Board's review, appraisal, and recommendations in energy related areas (i.e., other than nuclear weapons related programs) regarding:

- The appropriate roles and missions of the laboratories vis-à-vis industry and universities
- The scientific and technological capabilities of the laboratories
- The Department's policies and procedures with respect to the laboratories
- The effectiveness of the Department's use of the laboratories in meeting its energy objectives.

To perform the requested study, the Board established a Multiprogram Laboratory Panel, composed of both Board and non-Board members (list follows title page). The Panel was charged with reporting its findings to the full Board for review and approval prior to transmittal to the Deputy Secretary.

The Deputy Secretary asked for an interim report giving preliminary recommendations by March 1982 and a final report by September 1982. The Panel's Preliminary Report, issued in March 1982, addressed (a) the appropriate roles and missions of the national laboratory complex vis-à-vis universities and industry and (b) strategies, to be further studied, for making best use of the laboratory complex in a constrained programmatic/budgetary environment. The latter reflected the Panel's consideration of possible means of preserving the laboratory complex as a national asset in light of the Deputy Secretary's expressed concern "... that the scientific and technical strength of the laboratories may be eroded and that their ability to continue to contribute to the Nation's long-range energy needs may be diminished."

In developing its recommendations, the Panel took note of the Administration's proposal of December 17, 1981, to transfer the research and development functions of the Department of Energy (DOE) along with its laboratories to the Department of Commerce, the ongoing overall study of Federal laboratories by the Office of Science and Technology Policy, and the anticipated continuation of budget austerity with regard to Federal support of energy research and development. The Panel additionally consulted in detail with the Department's Headquarters and operations office staffs, the laboratory directors, other Federal agencies, and representatives from industry and universities. Moreover, two or more of the Panel members made full day visits to each of the laboratories, consulting with not only the Director but his principal staff as well.

The Panel found it very important to have a thorough understanding of the origin, development, and history of the laboratories; their changing missions and functions; and the Department's laboratory management processes. Because such background knowledge similarly is important to the reader's understanding of the Panel's findings and recommendations, Section III presents an extensive review of the laboratories in these regards. Readers who are thoroughly conversant with the laboratories need not review this material in detail.

III. OVERVIEW OF THE MULTIPROGRAM NATIONAL LABORATORY COMPLEX

A. Historical Perspective

Historically, 12 DOE laboratories were considerd multiprogram. Currently, three of these laboratories, Hanford Engineering Development Laboratory, Idaho Nuclear Engineering Laboratory, and Savannah River Laboratory, are focused almost exclusively in a single program area. This circumstance is not expected to change in the foreseeable future. In its study, therefore, the Panel decided not to include these laboratores (and, for the same reason, the Solar Energy Research Institute). Accordingly, the nine multiprogram laboratories considered by the Panel are:

- Ames Laboratory
- Argonne National Laboratory
- Brookhaven National Laboratory
- Los Alamos National Laboratory
- Lawrence Berkeley Laboratory
- Lawrence Livermore National Laboratory
- Oak Ridge National Laboratory
- Pacific Northwest Laboratory
- Sandia Laboratories

The national laboratory complex had its origins in the Manhattan Project and was formalized and expanded under the Atomic Energy Commission. The multidisciplinary character of the several laboratories sprang initially from the requirements of the atomic bomb project and related demands in radiation biology and health effects for expertise in virtually all the sciences (e.g., physics, chemistry, biology, engineering, and a wide spectrum of specialities within these disciplines). This feature of the laboratories was accentuated in response to the later inclusion of nuclear power research and development as a major laboratory mission. In this period, there evolved the concept of the laboratories as the guardian of "national trust" missions in physical sciences, including high energy and nuclear physics, and radiobiological sciences, including the lead Federal role in nuclear medicine research. Additionally in the past, the laboratories provided strong technical support and counsel in the Department's research and development policy and planning; in recent years the Department has made little use of this capability.

Under the Energy Research and Development Administration (ERDA) and, subsequently, the Department of Energy, the laboratories were uniquely equipped to contribute significantly to the greatly expanded Federal energy research and development thrusts, including their health, safety, and environmental aspects. Over the years the laboratories also undertook other peripheral, but nonetheless essential, functions. These include managing large research facilities and making them available to university and industry researchers, providing their special capabilities to assist other Federal agencies, and functioning as strong international links in scientific and technological areas. Regardless of their historical development, however, the basic questions today concern what scientific and technical needs of the country could be filled by the laboratories and, of these, which ones could best be filled by them.

By policy decision, the national laboratories were established as federally owned and funded facilities operated and staffed by private contractors. Even today they still represent the largest group, in terms of numbers, staffing, and funding, of government owned contractor operated facilities sponsored by the Federal Government or, indeed, by any nation in the world. The national laboratory complex is further characterized by a diversity of operating contractors, which include individual universities, university consortia, and industrial firms (e.g., Ames Laboratory is operated by Iowa State University; Brookhaven National Laboratory, by Associated Universities, Inc.; and Oak Ridge National Laboratory, by Union Carbide Nuclear Division). This diversity of operating contractors is reflected to a noticeable extent in the character of the individual laboratories. All the laboratories encompassed by this study are characterized by a high degree of multidisciplinarity, extensive research facilities, and an organizational and management structure that facilitates ready assembly of project and program teams as required. However, each laboratory differs in significant respects from the others. Some are highly focused on basic research (e.g., Ames Laboratory), others concentrate on applied research and development (e.g., Oak Ridge National Laboratory), and still others are well staffed and equipped in engineering disciplines (e.g., San-

dia Laboratories). The totality of multidisciplinary expertise, equipment, facilities, and breadth of capability at the national laboratories substantially exceeds that usually found in most university and industry laboratories. Capsule summaries of the individual laboratories are presented in Attachment B and summarized below.

B. The Individual Laboratories

The **Ames Laboratory** conducts basic research in materials and chemical sciences, relying upon existing capabilities for preparing high purity metals, alloys, compounds, and single crystals; and conducts materials related research and development in areas such as nondestructive testing of materials. The laboratory, sharing Iowa State University's campus, enjoys extensive cooperation with the University through year-round faculty appointments, graduate student training, and facility-sharing programs.

The **Argonne National Laboratory** (ANL) provides advanced nuclear technology research and development support to the breeder reactor and other fission reactor programs and maintains a substantial, diversified capability in physical and biological sciences in support of reactor efforts. In basic research, a major effort is materials research and development directed toward providing superior new materials for fission and breeder reactors, fusion devices, and advanced fossil energy systems. The laboratory has developed and operates research facilities such as the High Voltage Electron Microscope and the Intense Pulsed Neutron Source. It is now beginning fabrication of a major, user-oriented facility, the Argonne Tandem-Linear Accelerator System (ATLAS), which will be a national facility for heavy ion research in physics.

The **Brookhaven National Laboratory** (BNL) conceives, develops, constructs, and operates large, complex research facilities (e.g., the National Synchrotron Light Source and the Alternating Gradient Synchrotron) that are used to study fundamental properties of matter and are shared with university and industrial scientific communities. The laboratory conducts basic and applied research in technology base areas, both to support research at other facilities and to discover important new directions for research. Major disciplinary strength is found in the areas of high energy, nuclear, and solid-state physics; chemistry; and biology. Biological and medical programs include studies of the health effects of radiation and of chemical substances involved in the production and use of energy.

The **Lawrence Berkeley Laboratory** (LBL) conceives, develops, constructs, and operates large, complex research facilities, e.g., Bevalac and Super Heavy Ion Linear Accelerator (HILAC), that are shared with university and industrial scientific communities. The laboratory capitalizes on its co-location with the University of California at Berkeley to provide a diverse and flexible assembly of scientific talent for research and advanced development with major research programs in high energy physics, nuclear physics, basic energy sciences, conservation and solar energy, coal research, inertial confinement fusion, geochemistry, computer science, and mathematics.

The primary role of **Lawrence Livermore National Laboratory** (LLNL) is the research, development, and testing of nuclear weapons designs. Expertise developed in this area is also applied to related areas of defense research such as inertial confinement fusion, nonnuclear ordnance, and particle beam technology. LLNL also undertakes research and development technologies of national interest, primarily in the field of energy, where the skill or facilities requirements are unique and synergistic to the weapons effort. As a result, the Laboratory has ongoing programs in magnetic fusion energy, laser isotope separation, biomedical and environmental studies, in-situ coal gasification and oil shale retorting, energy storage systems, transportation energy conservation, and solar energy research and development.

The **Los Alamos National Laboratory's** (LANL) primary mission is the application of science and technology to problems of national security, that is, to the maintenance of a strong defense, the fulfillment of arms control commitments, and the guarantee of a secure energy supply for the future. Major programs include developing nuclear warheads, designing and testing advanced technology devices, and maintaining an innovative weapons design program. In nuclear fission, programs include testing advanced reactor fuel elements, modeling reactor accident results for the Nuclear Regulatory Commission, evaluating biomedical consequences of nuclear energy production, and developing effective nuclear waste disposal methods.

The **Oak Ridge National Laboratory** (ORNL) primarily supports the fission nuclear fuel cycle and magnetic fusion energy development (advanced toroidal devices such as Tokomak and Elmo Bumpy Torus) through scientific research and technology; identifies and solves generic research problems in energy technologies such as materials, separation techniques, chemical processes, and biotechnology; and is the major national source of production of stable and radioactive isotopes. Energy technology development at ORNL also includes other important efforts in residential and commercial energy conservation, renewable energy sources, ecology, biology, and coal conversion and utilization.

The mission of the Pacific Northwest Laboratory (PNL) is the advancement and use of scientific and engineering technology for national security and the nation's multiple energy needs. In accomplishing this mission, high priority is given to safe and reliable nuclear energy and to promising new concepts and technologies for operations at Hanford. Areas of disciplinary strengths and concentration include nuclear waste process development, nuclear fuel development and evaluation, spent-fuel storage and reprocessing, inhalation toxicology, bioelectromagnetics, biology, ecology, atmospheric sciences, corrosion chemistry, biomass research, nondestructive testing and evaluation, materials characterization and research, chemical engineering, health physics technology, and energy economics and policy analyses.

Sandia Laboratories' principal mission is research, development, and engineering of nuclear weapon systems, except for the nuclear explosive. Sandia is also responsible for major energy programs in fossil, solar, fission, and basic energy sciences. Its strength lies in its ability to conduct large, interdisciplinary engineering projects that are both technologically risky and sophisticated. Fundamental understanding and technological development are melded to create an environment conducive to generating new products and processes.

C. Current Status of the Laboratories

Funding and staffing at the multiprogram laboratories increased significantly under ERDA. The high level of staffing reached in the late 1970s later became a matter of concern within the Department of Energy; measures to control laboratory growth, largely successful, were instituted, and employment leveled off at about 41,000. The policies of the present administration, expressed through budgetary retrenchment in areas deemed within the responsibility and capability of industry, caught the laboratories overextended in areas no longer considered appropriate for Federal support. As a consequence, nondefense-related staffing of the laboratory complex at the end of the FY 1982 is lower by about 10% (3500 people) than in FY 1980. Significant staff reductions are possible during FY 1983, depending on the final budget. Staffing problems have not been uniformly distributed among the laboratories. The weapons laboratories were least impacted, although reductions are taking place in some energy research areas, notably in solar energy. The nonweapons laboratories are expected to be at 10% to 20% below peak employment by FY 1983.

D. Special Laboratory Roles

The laboratories commonly are perceived primarily as performers of research and development. However, they currently play additional significant roles that need to be evaluated in considering the future roles and missions of the laboratories. These current additional roles include the following.

Systems Engineers/Technical Consultants. Laboratories play the role of system engineers, advisors, and evaluators for DOE. This is particularly true in those areas where industry has an economic or proprietary interest and, if called upon, might be perceived to have a conflict of interest (e.g., coal conversion processes needing government funding, nuclear safety, etc.). The laboratories help the Department to be an informed buyer in making its commitments outside the laboratories. In this role, too, the laboratories address public health, safety, and environmental issues. Laboratories perform checks and gather data on existing systems and make technical assessments of safety and health-related work. For example, the laboratories have been called upon to prepare drafts of environmental impact assessments and statements. Again, these are areas where industry might be perceived to be less objective about results, were they to produce them. Because choosing areas where data are needed requires a detailed knowledge of rather large, complex engineering entities, the universities have normally been involved only in the basic research end of the spectrum.

Quick Response Service. Laboratories are frequently called upon to provide a fast start-up or apply their multidisciplinary expertise to meet quickly an urgent research and development or technical need. The most recent needs of this kind have been the Three Mile Island accident and the Strategic Petroleum Reserve fire. Many lesser ones involving technical problems occur on a far more frequent basis, and the laboratories are called upon to drop what they are doing and apply their resources to those problems to obtain a rapid and correct answer. The laboratories also have been requested to provide services that, while they have had some technical component to them, did not require innovative technologies or discoveries but rather quick application of knowledgeable manpower. For example, Oak Ridge National Laboratory has provided several technical assessments and analyses in support of residential conservation service legislation.

Stewardship. Laboratories are stewards of many special research facilities that are nationally and internationally unique or at least very rare. The laboratories maintain the continuity of long-term research and make the facilities available to a variety of institutions, usually universities but more recently to industry, even for proprietary research. These research facilities and resources include nuclear reactors, accelerators, atomic particle-scattering facilities, light sources, special equipment, national environmental research parks, and large animal populations.

Agents. For some years laboratories have acted as technical agents for DOE as it adopted a policy of decentralization. Laboratories were given lead missions involving broad technical management responsibilities for implementation planning, organizing, monitoring, and carrying out complex packages of research and development work for the Department, using explicit policy guidelines and budgets established by DOE Headquarters. Much of this included subcontracting a majority of the work to industry and universities.

Production. Some laboratories have unique capabilities to produce items of commerical value, such as radioactive and stable isotopes produced at Oak Ridge National Laboratory with annual sales of $15 million. Industry has not found it profitable to invest its own money for such purposes, but this is an area vital to health and industrial processes and for which there is an international market and competition.

Local and Regional Service. Laboratories, by reason of their geographical locations, have been consultants to state and local governments and have undertaken technical research specific to their geographical regions. Depending upon special circumstances, they provide coal support to other Federal activities in the vicinity and to the other local DOE operations offices in their roles as project managers when they need special technical work performed quickly to provide a basis for making decisions. Examples include assistance to several states by Ames Laboratory in the use of atomic emission and mass spectroscopy techniques for trace metal analysis of air and water; assistance to the city of Berkeley, California, by Lawrence Berkeley Laboratory in the form of technical advice and demonstrations with regard to building energy conservation; and assistance to New York State by Brookhaven National Laboratory in using concrete polymer developed at that laboratory on highway bridge repairs. Additionally, universities have aggregated some of their work around their neighboring DOE laboratories. For example, both Los Alamos National Laboratory and Sandia Laboratories have relationships with the University of New Mexico; Argonne National Laboratory and its associated universities have developed close interaction and mutual support.

Training and Education. Laboratories have frequently been involved in nationwide training and education programs. These include allowing doctoral work to be done at the laboratories, hiring and training postdoctoral students for short periods of time, and actually establishing education branches for use of special facilities at the laboratories as, for example, at Lawrence Livermore and Los Alamos National Laboratories.

Work for Other Federal Agencies. All the laboratories perform some work (10%-20%) for agencies other than DOE, usually because they have special facilities and capabilities or because the law intends it so [e.g., most laboratories perform work funded by the Nuclear Regulatory Commission (NRC), because the law requires DOE to make its laboratories available to NRC]. One example of work for another agency is the development by Sandia Laboratories for the National Oceanic and Atmospheric Administration of acoustic transmission systems for communicating data from ocean bottom instrumentation to surface receivers. Another example is the work for the National Institutes of Health by Lawrence Berkeley Laboratory involving biophysical studies on the effects of heavy ions and clinical trials of the effectiveness of heavy ions as a cancer treatment modality, both employing the Bevalac.

E. External Relationships

The laboratories have a long history of relationships with the university and industry communities through a variety of mechanisms. For some laboratories cooperation with universities has been particularly close because the operating contractor is a university or university consortium. In most laboratories, means are provided for large numbers of university faculty and students (up to 20% of full-time equivalent staff) to work at the laboratories for extended periods. University researchers commonly use unique facilities and equipment at the laboratories. Some laboratory research and development is subcontracted to universities. In FY 1981 this amounted to about $39 million in direct subcontracts plus the not readily calculable value of the universities' free access to unique laboratory research facilities. Laboratory relationships with industry, in general, have been less intimate, but nonetheless significant. Occasionally industry personnel work at the laboratories side by side with laboratory staff on problems of mutual interest. For example, as many as 11 industry personnel at a time from six private firms participated in this manner in Argonne National Laboratory's battery development program. Laboratory research and development subcontracting to industry is common. The best figures the Panel has been able to obtain suggest that the latter approximated $260 million in FY 1981. This work largely consisted of technical and engineering analyses and component and hardware development. In addition, procurements from industry approximated $640 million. In an effort to create closer ties and cooperation, the laboratories and the Industrial Research Institute have established a joint task force to explore and develop means of greater interaction. Close ties are also maintained with the international community through a variety of means, including staff exchanges and the training of foreign na-

tionals at laboratory facilities. Both university and industry scientists serve on outside review committees established by the laboratories to advise them on the quality and performance of their work although use of this process is somewhat spotty. In addition, to comply with the Stevenson-Wydler Technology Innovation Act of 1980, the laboratories have upgraded their technology transfer programs. Most of these external relationships are two-party, in the sense that they are focused on either industry or academia. The most important mechanisms are the following.

User Facilities. A prime purpose of national laboratories is to maintain and make available unique facilities needed by scientists and engineers in many institutions for their research and development work. The emphasis has been on use of facilities by individuals, mainly from universities, but industry use of these facilities is increasing. For example, Brookhaven's National Synchrotron Light Source has been used by 12 major companies, and Sandia's Combustion Research Facility, by seven companies.

Communications Services. Laboratories serve as catalysts and facilitators for scientific communication by (a) arranging a variety of ways for visitors and guests to spend time at a laboratory, often directly involved in laboratory programs, and encouraging laboratory personnel to visit industry and universities; (b) taking the initiative in setting up conferences and workshops on topics of national interest; and (c) helping to build and support communication networks that meet national needs, such as between academic disciplines, between industry and academia, and between policymakers and the research community.

Contracting. Laboratories contract with industry and universities for research and development, provide research and development support for the performers, and serve as a source of technical direction and quality assurance for government programs, a role that for several laboratories has grown considerably since the creation of DOE. On occasion, they contract from industry and utilities for research and development as well as perform work for other nonfederal sponsors (such as state and local governments). For example, Oak Ridge National Laboratory received contracts from 74 nonfederal sponsors in FY 1981 and FY 1982.

Other Partnership Arrangements. Other joint arrangements include (a) direct collaboration whereby researchers work together, most often on an informal personal basis since more formal arrangements can be cumbersome; and (b) complementary assistance whereby the partners help to meet each other's needs in such ways as providing technical assistance quickly, serving on advisory committees, reviewing draft reports and proposals, and working together on committees and panels and in scientific and professional societies.

Built-in Institutional Links. Each of the multiprogram DOE laboratories is, in fact, operated by a nongovernmental institution, a university or university assocation, or a profit or nonprofit firm. Many of these laboratories are also linked to associations of regional universities, and some have developed special links with institutions in their own neighborhood (e.g., Los Alamos and Sandia with the University of New Mexico and Oak Ridge with the Tennessee Valley Authority and the University of Tennessee).

Production Activities. In certain special cases, on behalf of DOE, laboratories are not just developers but also producers of devices and materials (e.g., the radioisotopes produced at Oak Ridge and Los Alamos). These external relationships of laboratories are discussed in considerably more detail in Volume II, Chapter 5.

Use of the Laboratories for Education and Training. National laboratories host a steady stream of scholars, teachers, and students. In many cases, these visits involve temporary appointments at the laboratory. Typically, for example, Oak Ridge, Argonne, and Brookhaven National Laboratories will each have about 1,000 university faculty members and students in residence for all or part of a year, participating in laboratory research programs and exchanging professional insights with laboratory staff. For instance, the Division of Educational Programs at Argonne operates eight programs for visiting faculty, eleven for graduate students, six for undergraduate students, and two for high school students. Guests from universities at Brookhaven during 1981 (including research collaborators) were affiliated with 123 U.S. colleges and universities and 46 foreign universities. Similarly, Lawrence Berkeley Laboratory customarily has on site 500 graduate students doing thesis research. These opportunities for participation and interchange bring many of the best minds in the nation to the national laboratories, and they contribute to building and maintaining a pool of trained manpower for energy research and development.

The roles of DOE laboratories in training industrial research and development personnel are limited. Because education and training are fundamental roles of universities in this country and because industrial firms often provide their own training programs for employees, specific training activities by a laboratory have generally been considered unnecessary and inappropriate. Under a particular set of circumstances, however, laboratories have taken on such responsibilities in the past, and they continue to offer a few short courses and other short-term training programs in specialized areas. These educational and training programs are discussed in more detail in Volume II, Chapters 5 and 6.

IV. THE APPROPRIATE ROLES AND MISSIONS OF THE LABORATORIES VIS-À-VIS UNIVERSITIES AND INDUSTRY

A. Assessment of Roles and Missions

The roles and missions of the laboratories, industry, and universities necessarily must be assessed in the context of the overall Federal energy research and development role as articulated by the Administration. In the Panel's understanding, the Federal policy emphasizes increased reliance on private initiatives for energy technology development and implementation. The Federal policy, however, recognizes an appropriate Federal role in long-range, high-risk, potentially high-payoff energy research and development where profit prospects are remote or where society at large rather than individual private investors would benefit from such research and development.

The comparative major capabilities and limitations of multiprogram laboratories, universities, and industry in the context of the Federal energy research and development role can be described with proximate confidence. The laboratories are well suited for basic and long-range, high-risk research and development, large multidisciplinary efforts, and operation of large capital-intensive research facilities, but they come up short in marketing/commercialization skills. Universities stand out for excellence in basic research and narrowly focused applied research and development, but they are not notably oriented toward market involvement or, with the exception of some sponsored research institutes, for large-scale multidisciplinary efforts. Industry stands out in development, demonstration, and commercialization activities and often displays impressive capabilities for large multidisciplinary efforts, but it tends to focus its basic research and high-risk research and development on corporate goals, unless funded by the Government.

Given these in part complementary and in part overlapping capabilities, the question at issue is how to make best use of the multiprogram national laboratories in the context of the overall energy-related national scientific and technological enterprise.

Each of the laboratories currently is identified with one or a few substantive areas of concentration. These core areas can be expected to remain central to any national energy policy for years to come and are widely recognized as areas of laboratory excellence. In each of these, the laboratories have established strong relations with the users of the research and development. In general, these core areas can be generically identified as follows:

Ames	— Fundamental Energy Science
Argonne	— Nuclear Energy, Fundamental Energy Science
Brookhaven	— Fundamental Energy Science
Lawrence Berkeley	— Fundamental Energy Science
Los Alamos	— Defense
Lawrence Livermore	— Defense
Oak Ridge	— Fundamental Energy Science, Magnetic Fusion, Nuclear Energy (fuel cycle, primarily)
Pacific Northwest	— Waste Management
Sandia	— Defense

As a first approximation, therefore, the role of the laboratories should encompass generically these core areas.

By virtue of the work they perform in their core areas, the laboratories develop expertise applicable to other areas (e.g., the drilling technology developed in the weapons laboratories can be applied in in-situ gasification). The question is, when should work in such other areas be assigned to the laboratories rather than to industry, universities, or nonprofit organizations? One way to resolve this question is to allow the laboratories to compete in these other areas with the other sectors in response to government requests for proposals, basing the competition on expertise and the likelihood that the results will be successfully transferred to the intended users. Short of this, the laboratories generally should be assigned research and development intended ultimately for market application when they have special expertise in the area. More specifically, research and development at the laboratories should be primarily in specific areas of science and technology that respond to:

- The Department's "national trust" missions
- Needs for which the laboratories' scientific or engineering capabilities for making salient contributions are demonstrably superior to those of universities and industry

- Long lead-time innovations requiring new scientific knowledge for which adequate private sector commitments and resources are unavailable
- Path-breaking basic research in support of government missions to which particular laboratory resources are matched
- Environmental and health research where performance by others would be seen as constituting a conflict of interest.

The proper role of DOE in energy research and development is to fund and manage those activities for which industry lacks incentives (e.g., environmental, health, and safety research and development) or for which the economic benefits, although substantial, are either sufficiently uncertain or so far in the future that industry chooses not to risk its own resources. In addition to the question of appropriate topics for Federal funding, there is the question of performance. Who is to perform the energy research and development that DOE sponsors? As a general guideline, DOE should choose the performer that can do the best job. Ability to do the job should be measured according to two variables, technical capability and ability to transfer the results to intended users. Further guidance on the choice of performer for a particular research and development task is given by considering the following three situations: (a) industry or universities have capabilities equal to those of the national laboratories, (b) one segment has the necessary capabilities whereas the others do not, and (c) the necessary capabilities do not exist.

Equal Capabilities. Situations involving equal capabilities need to be judged on a case-by-case basis. If the technology is intended for the market and private firms that have an interest in manufacturing or using the technology have the necessary skills and facilities, they should probably be assigned the work. If, however, the firms with the capability to perform the project are interested in it solely for the purpose of doing business with the Government, no special advantage accrues from assigning the work to them rather than to national laboratories.

Unequal Capabilities. In choices between potential contractors with unequal capabilities, generally, the work should go to the organization having the best capabilities. Building duplicate facilities or skills is, in most instances, a waste of the taxpayer's money. Exceptions are cases involving real or perceived conflicts of interest.

Capabilities Do Not Exist. Where capabilities do not exist, a case-by-case judgement is required. If government funding to create a private sector capability would result in leveraging of significant private funding or tightening the connection to production capability, then industry should be the choice. Otherwise the work should go to either universities or national laboratories, depending on the nature of the research. The creation of new national laboratories within the private sector is inconsistent with Administration policy concerning roles of Government versus those of the private sector. Similar considerations apply to universities. The Government should be alert to opportunities for building facilities and equipment to assist universities in their teaching and research mission.

B. Findings and Recommendations

1. Findings

- The multiprogram national laboratory complex constitutes an impressive national research and development asset. Moreover, it possesses capabilities for the performance of large-scale, long-term, high-risk multidisciplinary research and development; however, these characteristics in and of themselves do not uniquely define appropriate roles and missions for the national laboratory complex. The industry and university research establishments are capable of and often carry out work comparable to much of that performed by the national laboratories, albeit often with differing goals, objectives, and institutional settings. The issue at hand is how to make the best use of the existing research and development assets of the multiprogram laboratories in the context of the national scientific and technical enterprise.
- Current Administration policy calls for increased reliance upon the private sector for technological advancements but recognizes an appropriate Federal role in supporting long-range, high-risk, potentially high-payoff research and development of national interest beyond that which can be expected from the private sector. The Panel concludes that there exist areas of research and development that require the complementary capabilities of the university, industrial, and laboratory sectors.

2. Recommendations

In energy related areas, the Panel recommends the following functions as appropriate for performance by the national laboratory complex, subject to university and industry participation as noted.

Direct Functions

- Carry out core elements of the Department's traditional "national trust" fundamental research missions in the physical sciences, including high energy and nuclear physics, and the radiobiological sciences, including nuclear medicine; in so doing,
  - perform research utilizing their unique capital intensive research facilities to ensure that the

capabilities of the facilities and scientific staff evolve appropriately to meet the needs of university, industrial, and other Federal research communities.

— exercise stewardship of these facilities and provide associated technical expertise to enable their efficient use by these communities.

- Perform research and development on the health, safety, and environmental externalities incident to promising energy technologies under development (not necessarily limited to those enjoying government funding) whenever high scientific competence or specialized facilities are available at the laboratories or when performance of such work by industry or, where relevant, universities would pose an apparent or actual conflict of interest.
- Perform generic energy research and development where it is judged to be in the public interest or where for economic or technical reasons industry does not choose to support it.

Government funding may provide support for either universities, industry, or the national laboratories, consistent with:

i) Department utilization of the best available performertor the given task

ii) Cooperation with intended users of the technology in determining applications oriented work to be performed in the laboratories

iii) Industry access to the facilities and staff of government laboratories for research and development funded privately, or with government funds, under appropriate policy guidance.

Support Functions

- As requested and in conformance with explicit policy guidelines and budgets established by the Department, act as agents for the Department in exercising broad technical management responsibilities for complex packages of multilaboratory and/or sub-contracted research and development work.
- In accordance with applicable Department policy, make the special capabilities and expertise of the laboratories available for technical assistance and reimbursable research and development to other Federal agencies; state and local governments; and regional entities, universities, and industry.
- Within their areas of capability and expertise, contribute toward the education and training of scientists and engineers by providing opportunities for this purpose at the laboratories to university faculty and students, industrial professionals, and, in accordance with national policy, foreign nationals.
- Assist the Department in the discharge of its overall responsibilities by:
  - — providing technical counsel to the Department on national research and development policies and future directions
  - — acting as systems engineers, advisors, and evaluators for the Department in areas where such involvements by others would constitute an apparent or actual conflict of interest
  - — Providing a fast start-up or multidisciplinary approach not otherwise readily available to meet quickly an urgent or emergency need for research and development, technical expertise or timely and reliable data of a critical nature
  - — supporting fulfillment of international agreements.

V. THE SCIENTIFIC AND TECHNOLOGICAL CAPABILITIES OF THE LABORATORIES

A. Laboratory Resources

The multiprogram laboratories represent an accumulation of human and physical capabilities that have been built up over several decades. As a system, they are the largest concentration of such resources in the country and probably the world.

Within a total employment of about 40,000, the multiprogram laboratories employ 8500 full-time equivalent scientists and 5900 full-time equivalent engineers (Table 1). These are supported by an annual budget of close to $3 billion or about 9% of Federal expenditures for research and development. Each of the laboratories contains a broad variety of disciplines spanning the physical sciences and biosciences and engineering and includes a few social sciences.

Table 1 shows that the three weapons laboratories are also the three largest in employment, making up over half of the laboratories' total.

The current book value of the plant and equipment of the nine multiprogram laboratories is about $2.5 billion. The replacement cost of the facilities would be several times that. In addition to being well equipped, the multiprogram laboratories possess a number of unique facilities that attract many users from the private sector. The major facilities are listed in Attachment B. Examples of widely used facilities follow:

Argonne National Laboratory	Intense Pulsed-Neutron Source
Brookhaven National Laboratory	Medical Research Center National Synchrotron Light Source
Lawrence Berkeley Laboratory	National Center for Electron Microscopy 88-inch Cyclotron
Los Alamos National Laboratory	Meson Physics Facility
Oak Ridge National Laboratory	National Center for Small-Angle Scattering Research
Sandia Laboratories	Combustion Research Facility Central (Solar) Receiver Test Facility

Table 1. Number of scientists and engineers employed at the multiprogram laboratories[1] (full-time equivalents)

	Scientists	Engineers
Ames Laboratory	343	46
Argonne National Laboratory	1,035	605
Brookhaven National Laboratory	712	342
Lawrence Berkeley Laboratory	734	304
Lawrence Livermore National Laboratory[2]	1,600	1,105
Los Alamos National Laboratory[2]	1,725	905
Oak Ridge National Laboratory	950	660
Pacific Northwest Laboratory	525	340
Sandia Laboratories[2]	904	1,592
	8,528	5,899

[1]Based on data from the most recent institutional plans or from private communications from the laboratories.
[2]Approximately 50% of these scientists and engineers work in defense programs.

The laboratories are organized to respond quickly to the demands of the sponsoring agency to apply management and multidisciplinary talent to a technical problem. In recent years, there have been increasing tendencies to create multilaboratory programs or task forces to bring the best available talent to bear on a problem. A variety of management skills have been used to propose, design, construct, and operate the major facilities that form part of this complex. The laboratories generally turn to subcontractors in the private sector for detailed design and construction services; Sandia, for example, managed about $320 million of procurement in FY 1981.

The management resources of the laboratories are also utilized in their lead mission roles, tools for decentralizing program execution. The number of lead missions currently assigned to the multiprogram laboratories is 32. These include some major programs such as large component development at Argonne, liquid metal fast breeder reactor physics and safety at Argonne, consolidated (nuclear) fuel reprocessing at Oak Ridge, and photovoltaic engineering development at Sandia. Many minor programs, such as reduced-enrichment fuel for research reactors at Argonne, building ventilation at Lawrence Berkeley, and annual cycle energy system at Oak Ridge, are also included.

B. Assessment of Capabilities

The Deputy Secretary's charge in regard to the scientific and technological capabilities, taken to an extreme, would involve an extensive and in-depth analysis covering such questions as:

- Laboratory capabilities for program execution and project management
- The areas of greatest strength (and weakness) in laboratory functional capabilities (e.g., research vis-à-vis engineering development; among disciplines; or for small tasks versus complex, multiyear projects) as well as identification of any unique capabilities
- A comparison of the research performance and overall research capabilities of the laboratories with those of universities and industrial laboratories doing similar work
- A comparison of laboratory capabilities in project management with those of federally funded research and development centers.

Considering the multiplicity of research and development efforts carried out by the laboratories, it was obviously impossible for the Panel to assess systematically even representative samples of the efforts. Fortuitously, the Office of Energy Research recently completed a systematic evaluation of the Basic Energy Science (BES) program consisting of a sample of 129 projects (randomly selected to represent the balance among disciplines from a list of over 1200 completed projects) whose research results were in each case reviewed by panels of specialists. This study was carefully carried out by 180 reviewers from industry, universities, laboratories, and other affiliations (78% of which were from outside the laboratories) thus permitting reasonably objective comparisons of similar efforts carried out in the laboratories and in universities. The BES projects were selected from a range of disciplines in physical, chemical, biological, and engineering sciences that are representative of much of the research and development capabilities of the laboratories. The statistically analyzed results of this study show that laboratory performance compares very favorably with that of universities.

It must be cautioned that the BES program represents only roughly 5% of the efforts of the laboratories under study, and the projects were all relatively small compared with the sizes of projects represented in many other laboratory efforts. While the conclusions of the BES study are reasonably extended to all supporting research and possibly also to general science and environment categories, extrapolation of conclusions to the larger categories of effort (e.g., nuclear, magnetic fusion, and nonweapons defense activities) or to the somewhat smaller categories of energy technology efforts (solar, fossil, conservation, etc.) may be questioned. The Department may wish to carry outcomparable studies in other areas.

The Panel wishes to point out that it is not the *quality* of the laboratory work that is usually questioned; rather, most critical questioning seems to be directed at the appropriateness of what the laboratories have been doing. For example, Dr. Arthur Bueche's testimony for Congressional Committee hearings on "DOE national laboratory relationships with industry and the university community" and his answers to supplemental questions asked by the Committee concerned primarily the balance of work assignments among performers and the standards of utility by which energy research and development results should be judged. Thus, it may be that issues of mission appropriateness and concerns about a perceived overdiversification of the laboratories in recent years may have raised implicit questions about whether the laboratories' output in some areas, while technically sound, has been ill-conceived or poorly managed.

This observation, together with discussions with the Department's Headquarters and operations office staffs, significantly supplemented by detailed discussions at each of the laboratories with the Directors and their senior staff, led the Panel to question whether the existing institutional arrangements respecting the Depart-

ment's organization and management of the laboratories may in themselves be the most significant impediment to optimal utilization of the scientific and technological capabilities of the laboratories. One of the indicators of such an impediment is that the laboratory directors have rather little control over the research and development activities of their own laboratories. The totality of each laboratory's program is primarily the result of individual negotiations between Headquarters and the laboratories at individual staff levels rather than at management levels. By the same token, the Department's management has relatively little control over laboratory activities except through gross budget actions at highly aggregated program levels.

The Panel finds the Department's management of the laboratories in practice is highly disaggregated, a condition further exacerbated by layering and fractionation of research and development responsibilities. Prolonged budgetary and appropriations uncertainty and the pressure of repetitive crash readjustments in program priorities create an environment in which it would be easy for the laboratory to lose its sense of basic mission and its ability to effectively transfer technology, and thus to enter into fields not appropriate for Federal support.

The Panel is impressed by laboratory accomplishments, which are summarized in Attachment C. The Panel further finds, however, that full realization of the laboratories' capabilities requires new institutional arrangements as delineated below.

C. Findings and Recommendations

1. Findings

- Overall, the Panel finds the scientific and technological capabilities of the laboratories impressive, but DOE organizational inefficiencies and funding policies are obstacles to their full realization.
- The Panel is uniformly impressed with the qualities and resourcefulness of laboratory leadership.
- The scientific and technical resources of the laboratories, including their physical facilities, cannot be utilized effectively under prolonged budgetary uncertainty and the pressure of repetitive crash readjustments in program funding.
- Layering and fractionation of managerial and research and development responsibilities in DOE require the laboratories to interact with DOE on an excessive number of horizontal and vertical levels and with heavy reliance on negotiation. The absence of a coordination and resolution officer with full authority at the Headquarters level giving attention and support to the laboratory directors results in inefficient utilization of laboratory scientific and technical capabilities.

2. Recommendations

- Urge the Office of Management and Budget to support rolling two-year appropriations by Congress for research and development with carry over funding to stabilize Department and laboratory planning and program execution.
- Designate a high level official, such as a Deputy Undersecretary, whose sole function is to be the Chief Laboratory Executive with authority to help determine and defend the research and development budget; to allocate the resources; to decide where work is to be done; and to assess laboratory scientific, technical, and managerial performance.
- Consistent with the foregoing, modify the roles of the operations offices with respect to the laboratories to focus on management of the contracts with the laboratory operating contractors and to de-emphasize their function as policy and programmatic intermediaries between Headquarters and the laboratories.
- Arrange for the laboratory directors to have substantially more flexibility, within overall budgets and broad program guidelines, to reprogram assigned laboratory resources and to initiate or adapt programs in accordance with research and development opportunities. This reprogramming authority should be no less than 5% or more than 10% subject to the satisfactory completion of the original assigned program acitivity. If additional Congressional authorization for this reprogramming is needed, the Department should seek it.

VI. THE DEPARTMENT'S POLICIES AND PROCEDURES WITH RESPECT TO THE LABORATORIES

Under U.S. laws and the laboratories' operating contracts, the potential scope of the laboratories is quite broad, encompassing health and safety research and all areas of nuclear and nonnuclear energy and environmental research and development. DOE policies, however, have set limits on what is considered as appropriate work for the laboratories.

For purposes of contract administration, the DOE field operations offices oversee the laboratories. Thus, the Chicago Operations Office is contract administrator for Ames Laboratory, Argonne National Laboratory, and Brookhaven National Laboratory; Albuquerque Operations Office, for Los Alamos National Laboratory and Sandia Laboratories; Oak Ridge Operations Office, for Oak Ridge National Laboratory; San Francisco Operations Office, for Lawrence Berkeley Laboratory and Lawrence Livermore National Laboratory; and Richland Operations Office, for Pacific Northwest Laboratory.

For purposes of programmatic and institutional management, the laboratories report to the Director of Energy Research or to the program Assistant Secretary who funds the major share of the laboratory work. Thus, the Director of Energy Research is the "cognizant secretarial officer" for the Ames, Argonne, Brookhaven, Oak Ridge, and Lawrence Berkeley laboratories; the Assistant Secretary for Defense Programs, for the Los Alamos, Lawrence Livermore, and Sandia laboratories; and the Assistant Secretary for Nuclear Energy, for the Pacific Northwest Laboratory.

A. Management Policies and Procedures

The Institutional Planning Process. To manage this unique set of multiprogram laboratories, the Department employs several management processes. The basic strategic planning vehicle is the Institutional Plan. This is a long-range planning document through which the Director of Energy Research or the Assistant Secretaries for Defense Programs and Nuclear Energy, the other program Assistant Secretaries sponsoring work, the responsible operations office, and the laboratories reach agreement on the general types and levels of activity to be conducted at each laboratory through a five-year planning period. The plan is updated annually and is approved by the appropriate secretarial officer and reviewed by the Under Secretary. The approved plan provides guidance to the laboratory for long-range planning and budget preparation and for site development plans. In addition, it serves as the baseline for placement of work at the laboratory.

Another of the Department's management processes is the periodic appraisal of laboratory performance, both technical and administrative. The Department also makes an annual assessment of requirements for maintaining the laboratory physical plant and endeavors, through the budget process, to accommodate identified needs.

The New Work Assignment Procedure. Supplementing the Institutional Plan process is a new work assignment procedure for considering placement of types or levels of work at the laboratories not contemplated at the time of preparation of the Institutional Plan. Such requests are approved by an official at the assistant secretary level and/or the responsible operations office after evaluation of the suitability of placing the work at a laboratory as opposed to universities or industry and the suitability of the particular laboratory for conducting the work. It is DOE policy to give preference to the private sector in the assignment of work it is qualified to perform. However, because DOE contracting procedures are cumbersome, new work is sometimes awarded to a laboratory as a matter of contractual convenience.

The Panel notes in this regard that neither the Institutional Plan process nor the new work assignment procedure provides a means of assessing the suitability vis-à-vis university and industry capabilities of ongoing work at the laboratories that was initiated prior to the adoption of these management processes.

Policies on Work for Others. The laboratories are permitted, sometimes encouraged, and in certain cases (e.g., Nuclear Regulatory Commission) required to do work for other government agencies. Interagency agreements are set up between DOE and the agency requesting the work.

DOE policies on work for other Federal agencies are given in DOE Order 4300.2, which specifies the follow-

ing restrictions on non-DOE work: (1) it must be determined that private facilities and laboratories are not available to perform the work on a convenient basis and at a reasonable cost; (2) the non-DOE work will not interfere with DOE program activities; and (3) the work must be consistent with DOE's basic responsibilities.

The laboratories are also cautioned not to respond to requests for proposals open to the private sector.

Although other agencies have the statutory authority to request work from DOE, some agencies' policies may actually constrain the laboratories from receiving funds. For example, the *National Science Foundation Grant Policy Manual* (201.1d) specifies that in

> carrying out its statutory purposes, NSF is expressly authorized by its own statutory authority to support research performed by other Federal agencies. However, it presently is Foundation policy not to encourage research proposals from other Federal agencies except in pursuit of specific NSF objectives.

Policies on Technology Transfer. DOE's technology transfer policy implementing the Stevenson-Wydler Technology Innovation Act of 1980 is established in DOE Order 5800.1, "Research and Development Laboratory Technology Transfer Program," issued from Headquarters on March 25, 1982. This order requires the laboratories to conduct technology transfer activities including:

> a) assessement of R&D projects for applicability to the needs of the private sector and state and local governments; (b) application and/or adaption of research or technology into processes, products, and services for use by private sector and state and local governments; (c) technical assistance to the private sector and state and local governments in adapting federally developed technology for use; (d) cooperation with technology transfer brokers to move technology from the laboratories to the private sector and state and local governments; and (e) licensing of DOE-owned patent technology for commercial use.

Each laboratory is required to formulate an annual five-year technology transfer program plan and make an annual technology transfer program report.

It is too early to tell whether the Stevenson-Wydler Act will significantly increase technology transfer between the national laboratories and other sectors. At a minimum, the act requires the Government and its laboratories to put a high priority on technology transfer activities.

B. Assessment of Policies and Procedures

It is not an overstatement that the Department's approach to the laboratories can be characterized as micromanagerial in administrative and procedural matters and quite conservative in its policy constraints on the permitted scope of laboratory activities.

In the former area, the Panel recognizes that there are certain fundamental Federal requirements that must be accommodated and that certain of these derive from the Office of Management and Budget and the Congress. Nevertheless, the Panel finds it disturbing that Argonne National Laboratory, for example, is required to be responsive to 137 different DOE orders and policy issuances, entailing dedication of substantial manpower and funding for compliance, reports, and audits. Equally disturbing is the fact that Argonne receives its funding through 129 separate accounts which are noninterchangeable and require separate controls.

Micromanagement to this degree deprives the laboratory of virtually all flexibility for better management of its resources. Moreover, it results in a significant diversion of laboratory resources from research and development missions. In substance, it deprives the Department of the very benefits and advantages that the government owned contractor operated mode of operation is designed to provide.

Policy constraints upon the laboratories in general are less onerous but nonetheless counterproductive. These constraints lie primarily in the area of laboratory relationships with the private sector and thus adversely affect technology transfer. For example, Departmental policies either preclude or overly limit laboratory work for others, private consulting by laboratory employees, and laboratory responsiveness in appropriate circumstances to government sponsored requests for proposals. Undue restrictions on laboratory work for others, in particular, are counter productive to national technological interests. The scientific and technological capabilities of the laboratories, developed to a high degree of sophistication at public expense over several decades, can contribute significantly beyond the primary laboratory mission responsibilities to other critical areas of national needs supportive of increased innovation, productivity, and international competitiveness. Within reasonable limits, greater accessibility by others to the laboratories for such additional purposes would represent prudent use of this important component of the national technological enterprise.

In certain areas, it must be said in fairness the Department has made important strides. For example, with

respect to appraisal of laboratory performance, which has been somewhat loosely implemented in recent years, the ongoing effort to develop a Departmentwide systemized and codified appraisal procedure with appropriate management follow-up, when completed and implemented, should result in benefits to both the Department and the laboratories. Also, the recently issued class waiver of patent rights in the case of fully cost reimbursed private use of laboratory facilities is a significant advance, assuming it is vigorously pursued at the operations office level. Moreover, the recent DOE Order on technology transfer at least establishes this function as a formal part of the Department and laboratory mission, albeit no dedicated funding appears to be forthcoming as will be necessary if such a function is to become fully operational. The implementation and maturation over the past few years of the laboratory institutional planning process also has been a beneficial initiative. It offers some degree of desirable long-range research and development program planning at the laboratories, although the Panel notes that the tendency to employ the Institutional Plans as constraining budget documents rather than strategic planning vehicles needs to be resisted.

C. Findings and Recommendations

1. Findings

- The laboratories have become grossly overburdened with detailed reporting and other paperwork requirements, the utility of which frequently is not apparent and which unnecessarily divert resources from their research and development missions.
- The Department's laboratory Institutional Planning Process is proving itself valuable, both to DOE Headquarters and the laboratories, although care needs to be taken that it produces a workable plan and not a strait jacket.
- The Department's approach toward appraising laboratory performance has been somewhat lacking in systemization, codification, and management follow-up. The Panel is pleased to note that the Department is in the process of rectifying this situation.
- The Department's restrictions on laboratory work for others, particularly industry, are unnecessarily constraining. Among other things, such restrictions frustrate technology transfer efforts.
- The Department's patent policy, particularly in connection with laboratory work for others, has been among the salient barriers to cooperative relationships with industry and to effective technology transfer. The Panel notes with approval that the Department recently has taken steps to liberalize its policy in this area.

2. Recommendations

- Utilize the services of an outside audit contractor familiar with both Government and industry practices to conduct a thorough audit of paperwork requirements in the Headquarters/operations offices/laboratory chain of command.
- Strengthen laboratory Institutional Plans as long-range strategic planning documents, as components of the Department's planning process, and as vehicles for new initiative proposals; de-emphasize their use as constraining budget documents.
- To supplement internal appraisals of laboratory performance, the Department should convene panels from recognized scientific bodies, such as the National Academies of Science and Engineering, to conduct periodic (at intervals not greater than five years) technical audits of laboratory programs in connection with approved institutional plans.
- While maintaining priority status for essential Department missions, allow the laboratories to do more reimbursable work for others (other Federal agencies, state and local governments, and industry) be relaxing constraints on such work.
- Undertake a well-planned education program among Headquarters, operations office, and laboratory staff on the recently liberalized patent policy to ensure that it will be vigorously implemented. In parallel, ensure that the private sector understands the new policy.

57-279 O - 87 - 53

VII. THE EFFECTIVENESS OF THE DEPARTMENT'S USE OF THE LABORATORIES IN MEETING ITS ENERGY OBJECTIVES

The Department's effectiveness in making use of its laboratories is strongly conditioned by the roles and missions perceived for the laboratories, the organization and management arrangements for fully realizing the scientific and technological capabilities of the laboratories, and the Department's policies and procedures with respect to the laboratories.

A. Assessment of Effectiveness

In some respects, it appears the Department has been rather conservative in utilizing the laboratories' capabilities. For example, although the laboratories constitute an exceptional reserve of scientific and technical knowledge and expertise, in recent years the Department has made little or no use of their capability in Departmental research and development policy and planning. Participation of the laboratories in a consultative capacity in these respects would add an invaluable knowledge dimension to the Department's resources for these purposes.

Through overmanagement and underutilization, the Department has deprived itself and the nation of the best that the laboratories have to offer. In principle the Department adopted the laboratory lead mission concept and the concomitant policy of decentralization; in practice it prejudiced the concept through excessive fractionation of programs and vitiated the policy through inadequate delegation of program execution authority to the laboratories.

Whereas the Department made credible and often successful efforts to create important, highly capital intensive research facilities of national and even international significance, it chooses or is required to fund their operation at levels far lower than those commensurate with their capabilities. In FY 1982, for example, the utilization factor for high energy physics machines ranges from 40% to 45%.

The Department (and the Administration) recognizes the appropriate Federal role in and adequately supports long-range, high-risk potentially high-payoff research and development; however, it limits or precludes as a matter of policy the kinds of close relationships between the laboratories and industry that are necessary if the benefits of such research and development are to be practically realized. Thus, Departmental and national energy research and development objectives would be advanced if policy and procedural avenues were developed by which the laboratories could engage in joint ventures with industry involving test and pilot demonstrations. Similarly, permitting the laboratories to engage with industry in jointly or cooperatively responding to Federal agency technical requests for proposals would better ensure that Federal technical needs benefit from application of the broadest possible spectrum of national scientific and technical expertise. It is recognized that laboratories must participate fairly in vying with the private sector for government work and, therefore, that costing of laboratory work for these purposes must be calculated as nearly as possible on the same bases as is done in industry.

The Department also recognizes the role the laboratories can play in the education and training of scientists and engineers, but it does not exploit this capability to the full extent possible.

In the last analysis, effective use of the laboratories in technology areas is reflected most accurately by the success or lack thereof in the application of the results of laboratory research and development in the marketplace. Issuance of the DOE Order on technology transfer is a significant, but not sufficient, step in the right direction. A major management commitment, backed up by adequate resources, is required. Effective technology transfer is extremely difficult to achieve under the best circumstances. Even if the laboratories were exceptionally well attuned to this function (and they are not), extraordinary efforts will still be necessary to achieve even modest success. Complicating the problem is the fact that the multiprogram laboratories, along with other government laboratories, are constrained by traditional governmental policies and attitudes that inhibit effective technology transfer. Often government laboratories are not permitted to pursue research and development sufficiently far to establish reasonable evidence of technical and economic feasibility and thus to create private interest. Even if they are, industry often has great difficulty in obtaining the patent protection needed to justify its required further development and commercialization in-

vestment, a consideration that strongly inhibits effective technology transfer. The traditional arms-length relationship between government and industry is intrinsically an obstacle to effective technology transfer.

The Department must do much more to seek out and implement measures that will materially facilitate the technology transfer process.

B. Findings and Recommendations

1. Findings

- The Panel finds that the Department has been conservative in envisioning, not to mention implementing, policies by which the laboratories could be more effectively utilized. This has resulted in a lesser contribution by the laboratories toward meeting the Department's energy objectives than could otherwise be achieved.
- Contrary to past practices, the expertise of laboratory staff and directorate are not being utilized in establishing Department policy and directions for research and development.
- While laudable in principle, the Department's policy of assigning lead missions to the laboratories, has been, with few exceptions generally ineffective because of excessive fractionation of mission assignments, inadequate delegation of authority to the laboratories, and seeming lack of commitment to the policy by DOE management.
- Under present budgetary constraints a number of the specialized research facilities at the laboratories are being operated far below capacity.
- While use of the laboratories for contributing toward training scientists and engineers to meet the Nation's needs has grown in recent years, their use could increase.
- Research and development program planning does not consider adequately end-user views.
- Institutional and doctrinal barriers toward greater laboratory/industry cooperation continue to inhibit achievement of the Department's energy objectives in general and technology transfer efforts in particular.

2. Recommendations

- Establish a consultant group composed of all the laboratory directors to utilize more effectively laboratory resources in establishing the Department's research and development policy and directions.
- Implement vigorously the assignment of lead missions to the laboratories, defining these in terms of major applied programmatic missions, and provide for significantly greater laboratory discretion in allocation of resources (within overall Headquarters established budgets for the mission area) and in the selection of performers.
- In setting research priorities, give special weight to making optimal productive use of sophisticated equipment and facilities.
- Establish user groups reporting to the Department, similar to the High Energy Physics Advisory Panel and the Nuclear Science Advisory Committee, for all of the Department's major mission programs and facilities. These could be established independently for each program function or under the umbrella of an overall advisory group.
- Continue to support laboratory-university cooperation in the training of scientists and engineers through on-site participation by faculty and student in laboratory programs, term appointments, fellowships, etc.
- Permit and encourage joint ventures in selected projects with industry, including test and pilot demonstration (located at the laboratories or industrial sites) in order to test economic and to shorten the time lag for technology
- In areas of special laboratory exper capabilities, allow and encourage the labo to work more closely with industry by such as responding to requests for proposals fr dustry cooperative groups (e.g., American Societ of Heating, Refrigeration and Air-Conditioning Engineers; Electric Power Research Institute; and Gas Research Institute) and to work in partnership with industry in meeting technical needs of Federal agencies, as well as working directly for industry in connection with Federal agency requests for proposals.
- Permit each laboratory to use 1% to 2% of its capital and operating budget for independent research and development at the discretion of the laboratory director in order to enrich their research capabilities.
- Through a deliberate review and study by both the Department and the laboratories, identify institutional and doctrinal barriers to effective technology transfer and implement further actions to ameliorate these.

VIII. ALTERNATIVE STRATEGIES FOR MAKING BEST USE OF THE LABORATORIES IN A CONSTRAINED BUDGETARY ENVIRONMENT

A. Asssessment of Strategies

In its March 1982 Preliminary Report, the Panel identified strategies, to be further studied, for making best use of the laboratories in a constrained budgetary environment. In the course of its deliberations, the Panel concluded that two of these, the lead mission policy and freeing the laboratories to do much more work for others, had validity in their own right as contributors to more effective use of the laboratories. These have been discussed earlier. The other strategies envision preferential assignment to the laboratories of new research tasks in lieu of establishing new laboratories for these tasks, transfer to the laboratories of work presently franchised to other agencies, and shutting down or merging laboratories.

The Panel can see no justification currently or in the long run for the Department to establish new laboratories. The other two strategies present some benefits but also substantial risks.

Transferring work currently franchised to other agencies offers benefits in terms of more direct control over mission-supporting research, avoidance of bureaucratic interagency problems, and increased work volume to justify adequate staffing. Risks arise from vested laboratory interests in gaining new work at the expense of siting it in a better environment; from disruption of other agency programs; from possibly higher net costs compared with franchising; and from favoring the laboratories versus employing a highest- and best-use approach to the placement of Federal research work within the larger governmental system.

The benefits of shutting down or merging laboratories are mainly financial, with savings in operating expenses and overhead. The risks are various: irreversibility of decisions to terminate or consolidate; political controversy; adverse morale; possible undeserved termination of certain lines of research; negative impact on university and other present users of unique facilities; and consequences of accommodating to a forcing strategy for budgetary reasons at the expense of long-term expectations for a functioning and diversified laboratory system.

These latter strategies are viewed as drastic and to be considered only as a last resort.

B. Findings and Recommendations

1. Findings

- Some of the laboratories are currently being funded at levels close to the minimum consistent with maintaining their present competence and vitality.
- In view of their current broader responsibilities, any further funding reductions that would reduce laboratory staffing below the levels of the mid-1970's would demand that a number of measures, some drastic, be considered to preserve as much as possible the scientific and technical assets of the laboratory complex.

2. Recommendations

Certain measures that would help stabilize the laboratory complex in the event of further budgetary reductions have validity in their own right as contributors toward more effective use of the laboratories. These measures, which have been addressed earlier, relate to the lead mission policy and the freeing of the laboratories to do much more work for others. Additional measures recommended for consideration if necessary include:

- Transferring appropriate DOE-sponsored work now performed by other Federal agencies and directing additional work into the laboratories by assigning to them those new tasks for which new laboratories might otherwise be established.
- Narrowing the missions of the laboratories to correspond to the resources available.
- Closing particular laboratories or merging one or more of them with other DOE laboratories or even with other appropriate institutions outside the Department.

IX. ADDITIONAL CONSIDERATIONS

The Panel's Preliminary Report identified a number of issues to be addressed in the Final Report, most of which are covered in the Findings and Recommendations. This Section discusses those remaining issues not otherwise addressed in this Report.

A. Appropriate Size of the Laboratory Complex

As the Department's mission changes, it is reasonable to ask how large the laboratory complex should be and whether spending half of the entire DOE budget for research and development through the laboratories is still appropriate.

In FY 1981, about 51% of the Department's research and development budget went to the multiprogram laboratories, whereas only 33% went to industry and universities. On the face of it, the heavy reliance of DOE on its internal laboratories appears to be an anomaly when compared with the degree of internal spending of other Federal agencies. For example, the National Institutes of Health spend more than 90% of their budget externally. The anomaly is, however, more apparent than real. The reasons for the perceived difference can be found in the laboratories' involvement in the weapons programs and in the use of the multiprogram laboratories as conduits for DOE funding of industry and universities.

Over 42% of the multiprogram laboratories' funding in FY 1981 was for nuclear weapons, an area that seems inappropriate for industry and universities. If consideration is limited to DOE's energy research and development work, the multiprogram laboratories received approxi-mately 28% of DOE's budget, whereas industry and universities received 44%. But the multiprogram laboratories' share was actually less than 28% because of pass-through funds.

About 39% of the multiprogram laboratories' total operating budgets in FY 1981 was used for subcontracts and external procurement; most of this money went to industry and universities. Thus, the laboratories' in-house energy research and development probably amounts to no more than 20% of DOE's energy research and development budget. Considering the capabilities of the multiprogram laboratories for performing the long-term, high-risk energy R&D appropriate for Federal funding, it would appear that DOE has not made excessive use of its laboratories. With the trend to more defense spending and to fewer technology demonstrations, it is likely, and reasonable, that a larger percentage of the DOE budget will go to its multiprogram laboratories in the future.

B. Suitability of Agency Work Assignments to the Laboratories, Universities, and Industry

The Agency's laboratory Institutional Planning Process and New Work Assignment procedures are designed in part to control research and development activities assigned to the laboratories vis-à-vis universities and industry in accordance with prescribed criteria. The New Work Assignment procedure appears to accomplish this purpose for ad hoc proposals arising in the course of time. The Institutional Planning Process, however, appears to address this issue only at the margin (i.e., with respect to new work considered at the time the annual Institutional Plans are being developed). It therefore appears that there is no mechanism or process by which work ongoing at the laboratories over long periods of time (predating the foregoing processes and procedures) is reviewed for suitability for universities and industry in light of current circumstances.

Individual assignments to the laboratories are accomplished by a Work Proposal and Authorization System or another comparable mechanism. Review of these documents would provide a means of assessing current suitability of work assignments to the laboratories and should be done.

C. Effects on the Laboratories If the Board's Recommendations Detailed in the Federal Energy R&D Priorities Report Were to Be Implemented

The Panel's original intention to examine this matter was overtaken by programmatic and budgetary events; hence, it was determined such an analysis would not be useful.

ATTACHMENT A

DEPUTY SECRETARY'S CHARGE

THE SECRETARY OF ENERGY
WASHINGTON, D.C. 20585

Mr. Louis H. Roddis, Jr.
Chairman
Energy Research Advisory Board
110 Broad Street
Charleston, South Carolina 29401

Dear Mr. Roddis:

The multiprogram laboratories of the Department of Energy are an important national resource and play a key role in accomplishing the Department's missions. The Department is presently committed to focus its efforts on long-term, high-risk energy research and development and must adjust to an increasingly austere budget. Under these circumstances, I am concerned that the scientific and technical strength of the laboratories may be eroded and that their ability to continue to contribute to the Nation's long-range energy needs may be diminished.

Although the Energy Research Advisory Board is addressing the overall Federal role in energy R&D in your study of R&D priorities, the specific roles and missions of the multiprogram laboratories within this framework have not been examined. Therefore, I would appreciate the Board undertaking a comprehensive study that will help shape the future of the Department's multiprogram laboratories. I am particularly interested in your review, appraisal and recommendations regarding the scientific and technological capabilities of the laboratories, the appropriate roles and missions of the laboratories vis-a-vis industry and the universities, the Department's policies and procedures with respect to the laboratories, and the effectiveness of the Department's use of the laboratories in meeting our energy objectives. I fully expect additional questions to arise related to the laboratories and would appreciate interim reports as your study progresses, with one by March 1, 1982, giving preliminary recommendations.

A final report should be completed by September 1982. I realize that this is a major undertaking in addition to the Board's current efforts, but request that you give it a high priority. You can be assured of the full cooperation and assistance of the Department.

By copy of this letter, I am requesting the Director of the Office of Energy Research, the Assistant Secretaries, Operations Office Managers and multiprogram laboratory Directors to give you their fullest cooperation and support. The Board's efforts should also be coordinated with the Director of the Office

of Energy Research who will provide the necessary resources for the study and will be conducting additional related reviews at my request.

Sincerely,

W. Kenneth Davis
Deputy Secretary

AMES LABORATORY
Ames, Iowa

The Ames Laboratory conducts basic research in materials and chemical sciences relying upon existing capabilities for preparing high purity metals, alloys, compounds and single crystals, and conducts materials related research and development in areas such as nondestructive testing of materials. Smaller but unique and vigorous capabilities are maintained in high energy physics, nuclear physics, applied mathematics, coal preparation science, and solar technology. The laboratory enjoys extensive cooperations with Iowa State University through year-round faculty appointment, graduate student training, and facilities sharing programs. An effective summer research participation program for undergraduate students and faculty members (primarily from non-local institutions) is maintained by the laboratory to the mutual benefits of it, the participants, and their institutions. The Ames Laboratory actively disseminates the results of its work throughout the scientific and technological communities by the distribution of technical publications, the giving of invited presentations on technologically important topics, the consulting activities of laboratory staff members, the conduct of cooperative projects with industrial and other governmental concerns, and participation in the Federal Laboratory Consortium.

ARGONNE NATIONAL LABORATORY
Argonne, Illinois

The Argonne National Laboratory (ANL) provides advanced nuclear technology research and developmental support to the breeder reactor and other fission reactor programs, and maintains a substantial, diversified capability in physical and biological sciences in support of reactor efforts. Future efforts in the fossil area center on advanced process development, the materials technology, and instrumentation and controls systems engineering. In basic research, the largest effort is in the area of general materials studies. High energy physics and nuclear physics will continue to play a significant role.The consequences of the utilization of particular energy technologies are addressed through studies of health-related problems and the environment. The laboratory has a program to work closely with university professors on sabbatical leaves and sponsors a variety of programs providing opportunities for students through student-laboratory staff interaction.

Argonne is engaging in a number of activities aimed at improving industrial interactions, including involvement in the joint IRI/National Laboratory Task Force, as well as others

BROOKHAVEN NATIONAL LABORATORY
Upton, New York

The Brookhaven National Laboratory (BNL) conceives, develops, constructs, and operates complex large research facilities which are used to study fundamental properties of matter and are shared with university and industrial scientific communities (e.g., the National Synchrotron Light Source and the Alternating Gradient Synchrotron). The laboratory conducts basic and applied research in technology base areas, in support of research facilities, and to discover important new directions for research. Major disciplinary strength is found in the areas of high energy, nuclear and solid state physics, chemistry, and biology. Biological and medical programs include studies of the effects of radiation and of chemical substances involved in the production and use of energy. Other research programs include meteorological dispersion, atmospheric chemistry, pulmonary physiology, and inhalation toxicology. The National Synchrotron Light Source gives the laboratory a unique position in the breadth of sophisticated facilities available to all areas of the physical and biological sciences. Over 1,000 faculty and 160 students have guest appointments enabling them to carry out research at BNL facilities. In addition, there are five different programs which provide 150 students with a variety of training opportunities. The National Synchrotron Light Source will greatly increase the number of faculty and students carrying out research programs at the laboratory. This facility will also be used extensively by industrial scientists; presently, nine of the 29 initial beam lines at the facility are partially or completely supported by the industrial community.

Statistics:

	FY 1982 Estimated:
DOE Operating Budget Costs:	$125 M
Staffing (Full-Time Equivalent):	3,300
Capital Investment (Plant and Equipment):	$469 M

LAWRENCE BERKELEY LABORATORY
Berkeley, California

The Lawerence Berkeley Laboratory (LBL) conceives, develops, constructs, and operates complex large research facilities which are shared with university and industrial scientific communities (e.g., Bevalac and Super HILAC). The laboratory capitalizes on its co-location with the University of California to provide a broad range and flexible pool of the scientific talent for research and advanced development with major research programs in high-energy physics, nuclear physics, basic energy sciences, conservation and solar energy, coal research, interial confinement fusion, geochemistry, computer science, and mathematics. LBL has a role in the training of the next generation of scientists and engineers for careers in advanced energy research and technology. Over 500 resident graduate students conduct thesis research at the laboratory and many more use its facilities or perform collaborative research. Participation in energy research programs provides these students with skills in high demand by energy industries. The flow of Ph.D.'s to industry is one of many forms of technology transfer that allows LBL to maintain close and supportive relationships with industry.

Statistics:	**FY 1982 (Estimated):**
DOE Operating Budget Costs:	$84 M
Staffing (Full-Time Equivalent):	2,524

LAWRENCE LIVERMORE NATIONAL LABORATORY
Livermore, California

The primary role of Lawrence Livermore National Laboratory (LLNL) is the research, development, and test of nuclear weapons designs. Expertise developed in this area is also supplied to related areas of defense research such as inertial confinement fusion, nonnuclear ordnance, and particle-beam technology. LLNL also undertakes research and development technologies of national interest, primarily in the field of energy, where the skill or facilities requirements are unique and synergistic to the on-going weapons effort. As a result the Laboratory has active on-going programs in magnetic fusion energy, laser isotope separation, biomedical and environmental studies, in-situ coal gasification and oil shale retorting, energy storage systems, transportion energy conservation, and solar energy research and development. Within these programs, LLNL interacts with both universities and private industry through faculty/student training, consulting, and technology transfer activities.

LOS ALAMOS NATIONAL LABORATORY
Los Alamos, New Mexico

The Los Alamos National Laboratory's (LANL) primary mission is the application of science and technology to problems of national security, that is, to the maintenance of a strong defense, the fulfillment of arms control commitments,and the guarantee of a secure energy supply for the future. In carrying out this mission, the laboratory serves as a liaison between research in academia and industry and complements the activities of both. Major programs include developing nuclear warheads, designing and testing advanced technology concepts, and maintaining an innovative weapons design program. In nuclear fission,programs include separating isotopes of uranium by laser induction, testing advanced reactor fuel elements, modeling reactor accident results for the Nuclear Regulatory Commission, evaluating biomedical consequences of nuclear energy production, and developing effective nuclear waste disposal methods. In nuclear fusion, programs include magnetically confined plasma devices (especially high-beta devices), laser-induced fusion, and safe handling techniques for large quantities of tritium. Other programs include nonnuclear energy, basic energy science, and technology utilization.

Statistics:

	FY 1982 (Estimated):
DOE Operating Budget Costs:	$420 M

OAK RIDGE NATIONAL LABORATORY
Oak Ridge, Tennessee

The Oak Ridge National Laboratory (ORNL) primarily supports the fission nuclear fuel cycle and magnetic fusion energy development (advanced toriodal devices,such as Tokomak and Elmo Bumpy Torus) through scientific research and technology; identifies and solves generic research problems in energy technologies such as materials, separation techniques, chemical processes and biotechnology; and is the major national source of production of stable and radioactive isotopes. Energy technology development at ORNL also includes other important efforts in residential and commercial energy conservation, renewable energy sources, and coal conversion and utilization. ORNL expends special effort to involve industry in its programs and to encourage cooperative uses of facilities, both formally in users' groups and informally through professional contacts and participation. Similarly, the Laboratory provides universities with ready access to major research facilities, state-of-the-art research capabilities, training facilities for faculty and students, and an opportunity for collaborative research in areas where these sources are not available to universities.

Statistics:	**FY 1982 (Estimated):**
DOE Operating Budget Costs:	$278 M[1]

PACIFIC NORTHWEST LABORATORY
Richland, Washington

The mission of the Pacific Northwest Laboratory (PNL) is the advancement and use of multi-energy scientific and engineering technology for national security and the nation's energy needs. In accomplishing this mission, high priority is given to safe and reliable nuclear energy, and to promising new concepts and technologies for operations at Hanford. Areas of disciplinary strengths and concentration include nuclear waste process development, nuclear fuel development and evaluation, spent fuel storage reprocessing, inhalation toxicology, bioelectromagnetics, biology, ecology, atmospheric sciences, corrosion chemistry, biomass research, nondestructive testing and evaluation, materials characterization and research, chemical engineering, health physics technology, and energy economics and policy analyses. The laboratory provides a core capability for effectively utilizing the strengths of the universities and the private sector and has traditionally developed and maintained strong ties with the academic community. That resource is utilized through cooperative exploratory research efforts to accelerate application of new ideas, scientific research support to PNL efforts on team assignments, and exchange of staff and student research. Industry and utilities participate with PNL staff in efforts to develop advanced technology, to improve existing instruments or develop new ones,and to investigate and demonstrate energy conservation and conversion techniques.

Major User Facilities:

Critical Mass Laboratory

SANDIA LABORATORIES
Albuquerque, New Mexico; Livermore, California; Tonopah, Nevada

Sandia Laboratories' principal mission has been and remains research, development, and engineering of nuclear weapon systems, except for the nuclear explosive. The result of this effort is the existence of a national stockpile of nuclear weapons that are safe, secure, reliable, under strict control, and operationally ready. Sandia is also responsible for major energy programs in fossil, solar, fission, and basic energy sciences. Its strength lies in its ability to conduct large, interdisciplinary engineering projects that are both technologically "risky" and sophisticated. Fundamental understanding and technological development are melded to create an environment conducive to generating new products and processes that are unlikely to be produced in either university or industrial laboratories. These new technologies are transmitted to the private sector through journals, workshops, and other information transfer mechanisms, and significantly contribute to the nation's scientific and economic prosperity.

Statistics:	FY 1982 (Estimated):
DOE Operating Budget Costs:	$610 M
Staffing (Full-Time Equivalent):	7,950

ATTACHMENT C

Significant Accomplishments Illustrative of Multiprogram National Laboratory Research

AMES LABORATORY

- The Ames Laboratory developed efficient reduction and purification processes for uranium, thorium, the rare earths, zirconium, hafnium, yttrium, and vanadium. All of the processes have been adopted by industry, and all are in use today. Essentially all of the uranium used in the Western world has been prepared by the Ames process, and the entire rare earth industry is largely dependent upon the basic separations and chemical, metallurgical, and materials characterization achievements of this Laboratory (1940 to present).
- The development of the inductively coupled plasma atomic-emission spectroscopy method for multi-element analysis was carried out at the Laboratory. The method is very fast, requires minute amounts of sample, and permits simultaneous identification of up to 50 elements: for most of these elements, this method is more sensitive than any other. Commercial instruments based on this development have been introduced: six U.S. and 11 foreign companies are now marketing such instruments at a sales rate of about $100 million per year (1970s).
- Development of a ductile, composite superconducting wire suitable for large-scale magnets in the 12- to 14-tesla range was carried out by an interdisciplinary team of metallurgists and solid state physicists at Ames Laboratory. The material is easy to fabricate and has the high strength and strain tolerance needed for toroidal field magnets in Tokamak fusion reactors (1970s to present).
- The Ames Laboratory developed the basic science for sampling, isolating, and quantitating the trace organic compounds in water. The isolation techniques have increased detection power approximately 10,000-fold for most compounds of environmental interest. The methodology has been adopted nationally and internationally by government, university, and industrial laboratories (mid to late 1970s).
- Recently a reactive radio frequency sputtering method for the preparation of hydrogenated amorphous silicon films for solar cells was developed here. The method permits the preparation of large-area films needed for solar panels while retaining the careful control of the local environment of the hydrogen ions, which is needed for high performance (1978 to present).
- Very recently a method based on high-resolution solid state nuclear magnetic resonance in coal samples has been developed for determining the sizes of the polynuclear aromatic rings in the molecular structure of coal. These results, compared with similar results on liquid fuels produced from coal, are used to study the effects of the chemical processing steps in liquefaction (1978-1980).
- The Laboratory has also recently completed the development of a laser/mass spectrometer probe capable of detecting 62 elements present in concentrations as low as 1 ppb in phases of solids whose dimensions are as small as 10 to 20 μm and it is applicable to metals, semiconductors, and insulators. Accurate analyses can be made without the use of standards (mid-1970s to present).
- Chemical engineers and materials chemists at the Ames Laboratory have developed methods for improved control of the complex chemical equilibrium governing the separation of plutonium from uranium in fuel processing. The programs developed in the work are now being used in nuclear safety and nuclear safeguards programs in the United States (1973-1976).
- The development of a liquid junction solar cell using WSe_2 and $MoSe_2$ with efficiences of 10% and 9.5% and no detectable photocorrosion of the electrodes after extended illumination was recently carried out by an interdisciplinary group from the Materials Chemistry and Solid State Physics divisions at Ames (1977-1980).
- Ames Laboratory scientists are responsible for the recent development of a provisional international practical temperature scale for use by the entire scientific community. A large portion of fundamental research between 0.5 and 35 K was done by the Laboratory, and the scale was adopted by the International Commission on Weights and Measures (CIPM) (1975-1976).

ARGONNE NATIONAL LABORATORY

- Water-cooled nuclear reactor research, design, and development at Argonne National Laboratory contributed significantly to the establishment of the nuclear power industry and in the nuclear-powered submarine. The Laboratory still provides reactor and reactor waste safety information (1946 to present). This capability was applied to the following projects:
  1. design of the first land-based prototype submarine reactor,
  2. design of the first reactor using heavy water as a moderator and coolant,
  3. basic design of the Savannah River production reactors, and
  4. development of the boiling water reactor concept [Boiling Reactor Experiments (BORAX), Experimental Boiling Water Reactor (EBWR)].

- Liquid-metal Cooled Fast Breeder Reactor (LMFBR) research, design, and development at Argonne provided the technology foundation for these reactors and continues to provide component and materials testing and evaluation. It has accumulated 16 years of LMFBR operational experience in the production of electricity. This research produced the following advances:
  1. design of the first successful breeder reactor (EBR-I), which produced the first usable amounts of nuclear-generated electricity;
  2. development of fast reactor and high-temperature reactor fuel materials; and
  3. development of the world's first transient reactor test facility (TREAT) to study fuel behavior during sudden power surges (1946 to present).

- A prototype superconducting linear heavy-ion accelerator is operational. When a total of seven modules are completed, the Argonne Tandem-Linac Accelerator System (ATLAS) will be able to provide 1.5 GeV particles, previously unavailable, that will improve understanding of nuclear binding forces (1979 to present).

- Intense Pulsed Neutron Source-I (IPNS-I) provides the world's most powerful source of non-reactor neutrons, which will be used to study radiation effects in fission and fusion reactor materials. Other applications will include areas of physics, chemistry, and biology (1971 to present).

- Zero Gradient Synchrotron (ZGS) acceleration of polarized protons was used to study spin-spin interaction between protons at high energy. Contrary to the existing belief, spin effects were shown to be large (1971-1979).

- Liposome encapsulation, the technique of coating minute amounts of a drug with naturally occurring fatty substances called phospholipids, was developed at Argonne. The microscopic capsules formed by this technique penetrate individual cells, where the fatty coating is dissolved by enzymes and the drug is allowed to do its work without having been weakened or diluted by the body's defense systems. When applied to cancer chemotherapy,liposome encapsulation allows the destruction of diseased cells from within, while leaving nearby cells unharmed. Eleven companies are currently using the technique to improve the efficiency of their anti-cancer agents (1973 to present).

- ISO-DALT, a two-dimensional electrophoretic system that separates and maps human serum proteins together with TYCHO image analysis and the KEPLER data base, will become a powerful diagnostic tool for extremely early detection of many diseases in man and will be applicable to large populations (1978 to present).

- Mathematical software has been designed and developed, including EISPACK for eigenanalysis, FUNPACK for approximations of special functions, LINPACK for solution of linear systems, MINPACK for numerical optimization, and SPEAKEASY for matrix manipulations. There is also AURA, which functions as an "automated reasoning assistant" and interacts with the scientist to solve problems. Distribution on EISPACK alone includes over 1000 research centers in over 70 countries (1972 to present).

- The world's largest high-field superconducting magnets, used in magnetohydrodynamics generators of electricity and in high-energy-physics bubble chamber experiments, have been designed and developed (1963 to present).

- Fluidized-bed combustion is a technology that has been developed to permit the use of high sulfur coal. Ninety percent of the sulfur combines with limestone during combustion, thereby reducing air pollution. Attention is now focused on recycling the limestone (1963 to present).

BROOKHAVEN NATIONAL LABORATORY

- The large particle accelerators that Brookhaven National Laboratory (BNL) has designed, built, and operated as national facilities have been the sources of many discoveries in particle physics which have led to a deeper understanding about the nature of matter. The first observation of a charmed baryon was made at BNL; and two recent Nobel prizes in physics, 1976 and 1980, were awarded for work carried out at BNL: the discovery of the J/psi particle in 1974 and the experiment which showed the violation of a fundamental symmetry principle in 1963.

- The magnetic principle of alternating gradient strong focusing discovered at BNL has been, and continues to be, the critical advance upon which construction of synchrotrons capable of accelerating protons to 100's of GeV depends. This fundamental discovery had two important consequences: it greatly reduced the cost of accelerators by allowing much smaller aperatures, and it provided a means of transporting extracted or secondary beams (produced by interactions of the primary beam with a target) to experimental apparatus located far from the accelerator. Both of these applications are essential to all modern proton synchrotrons, which now operate at energies as high as 500 GeV (1952 to present).

- Research reactors developed at BNL have consistently been at the forefront of design of these very important research devices. The Brookhaven graphite research reactor in 1950 became the first peace-time research reactor; it supported most of the free world's neutron beam research until 1966, when the Brookhaven High Flux Beam Reactor (HFBR) came on line. The HFBR is now the nation's most sophisticated and most heavily used reactor for neutron beam research. Recent improvements include increasing the power by 50% and installing a cold neutron source (i.e., a source of very-low-energy neutrons used in solid-state physics research); these improvements assure continued preeminence in the research reactor field.

- Neutron cross section experiments and criticality experiments on the properties of lattices of uranium rods in water conducted at BNL provided the basis for the design of light water reactors that now produce most of the world's nuclear-generated electricity. In addition, the compilation, evaluation, and storage of data from the neutron cross section experiments and, more recently, from other nuclear experiments have led to the creation of a central repository for most of the nuclear physics data generated throughout the world (1950s to present).

- Neutron scattering experiments at BNL's High Flux Beam Reactor have definitely established the nature of the magnetic state and its competition with superconductivity. This crucial step in relating these two very fundamental and technologically important properties of materials will eventually lead to deeper understanding and more sophisticated applications of these properties (1976 to present).

- By the middle of the 1970s, sufficient data were obtained from a 600-ton solar neutrino detector situated 1 mile underground to show that either our current views of the details of the nuclear reactions generating the sun's energy are incorrect or that our understanding of the fundamental properties of neutrinos is not complete. Since both of these possibilities are of great interest, a new experiment designed to eliminate one of them is underway.

- The first demonstrated transformation of human cells in culture by ultra-violet light was shown at BNL; this discovery now opens the way for laboratory studies of cancer-producing mechanisms (1980 to present).

- The first correlation between the ability to repair damage to DNA and the life span of different mammalian species was discovered by a BNL scientist who is now investigating the relationship of DNA repair to aging in humans (1974 to present).

- The invention at BNL of a procedure by which the short-lived radiopharmaceutical ^{99m}Te could be effectively distributed and used by the medical community started a new generation of nuclear medicine applications. This isotope continues to account for approximately 80% of the one mission administrations of radiopharmaceuticals per year in the U.S. and is the basis of a $100 million commercial enterprise, domestically.

BROOKHAVEN NATIONAL LABORATORY (Continued)

• The labeling of 2-fluro-2-deoxy-d-glucose with radioactive ^{18}F at BNL and use of this radiopharmaceutical in conjunction with positron-emission transaxial tomography (PETT) has initiated widespread activity in many new areas of medical research: measurement of regional metabolic activity at accurately determined locations inside the brain is now possible. The technique has led to a much detailed understanding of a whole range of phenomena (e.g., drug response) and diseases (e.g., senility, stroke, and schizophrenia) that affect the brain. The National Institutes of Health (NIH) are now supporting about ten centers to carry out this type of work (1976 to present).

LAWRENCE BERKELEY LABORATORY

- The Lawrence Berkeley Laboratory (LBL) has been responsible for numerous major advances including the invention of the cyclotron, the linear accelerator, the synchrotron, and continuing contributions to new particle accelerator concepts and construction projects (1929 to present).
- The creation and identification of 15 new chemical elements, including plutonium, by nuclear synthesis was carried out by scientists at LBL (1940-1976).
- Particle research conducted by scientists at the Laboratory led to the discovery of the antiproton and numerous excited states of the fundamental particles (1955-1965).
- The Laboratory became one of the world's major centers of heavy-ion nuclear physics research by (1) adapting the 88-Inch Cyclotron to the acceleration of heavy ions (1971); (2) connecting the SuperHILAC heavy-ion accelerator to the Bevatron to make the Bevalac (1972); and (3) improving the Bevalac (1981) to provide acceleration of ions as heavy as uranium to multi-billion-volt energies, a capability unavailable anywhere else in the world. SuperHILAC, Bevalac, and 88-Inch Cyclotron accelerators serve as national facilities for nuclear physics and biomedical research (1971 to present).
- The LBL was responsible for the founding of the National Center for Electron Microscopy equipped with instruments of highest energy and highest resolution (1980 to present).
- The Laboratory was also responsible for the founding of the science of nuclear medicine (1935), the continued development of instruments and techniques for the beneficial use of gamma and particle radiations (1935 to present), and the exploration of use of heavy ions for treatment of cancer.
- The Laboratory has contributed significantly to discoveries and developments in high energy physics: for example, discovery of the Ψ family of particles, the discovery of charmed particles, the design and construction (with Stanford Linear Accelerator Center) of the Positron-Electron Project accelerator, the design and construction of the Mark I and II massive detector systems, the design of the Time Projection Chamber superconducting magnet, and the development of stochastic beam cooling (1974 to present).
- The Laboratory has also done research and development on particle injection into fusion reactors for heating and fueling and design and construction of neutral beam injectors for Lawrence Livermore National Laboratory's 2X-IIB, Princeton's Tokomak, and General Atomic's Doublet III (1974-1981).
- The large-scale field experiment was conducted in an iron mine in Stripa,Sweden, to measure rock characteristics significant to underground storage of nuclear wastes (1976).
- The LBL has been responsible for the development of instruments now used in hundreds of university and corporate laboratories for precise measurement of gamma radiation, x-rays, nuclear particles, chemical elements, chemical compounds, magnetic field strengths, and other properties (1950-present).

LAWRENCE LIVERMORE NATIONAL LABORATORY

Weapons

- Since its establishment in 1952, LLNL, in conjunction with Los Alamos and Sandia, has continued to function as an integral scientific and technical element of the nation's nuclear weapons program including all facets of nuclear weapon technology and the supporting scientific and engineering disciplines. Particularly, significant achievements have been made in such areas as reduction in size and weight, and enhanced safety, flexibility, and military effectiveness of nuclear weapons. These advances in design have enabled the defense community to provide the nation with increasingly effective warhead capabilities for its nuclear weapons systems.

Nonweapons

- Under inertial confinement fusion, LLNL developed the technology for 100 TW Nd: glass laser systems. This technology, now adopted as the international workhorse for ICF research, was successfully transferred to U.S. industry in 1975. In addition, LLNL developed the first ultrafast (~20 psec) x-ray streak camera (now becoming commercialized) and the first use of micro-fabrication technology for high resolution imaging of alpha particles and x-rays (1976-1978). In integrated fusion experiments, the Laboratory provided the first confirmation of laser induced thermonuclear reactions (1975), the first demonstration of energy scalable ablative implosions (1976), and achieved a systematic scaling of imploded fuel density, up to 100 times liquid density, on the Shiva laser facility (1978-1979). Also definitive improvements in target performance at visible and ultraviolet wavelengths were demonstrated on the Argus laser facility. For fusion energy applications, LLNL researchers conceived and assessed the excimer laser driver and the HYLIFE reaction chamber, which features a long-lived (30 year) liquid lithium "first wall" (1977-1981).
- Within the Atomic Vapor Laser Isotope Separation (AVLIS) Program, researchers separated uranium isotopes (1974); demonstrated macroscopic uranium enrichment utilizing critical subsystems scalable to production plant size (1978); developed a high-power tunable (isotopically selective) laser system which is economically competitive (1981); and activated a full-scale uranium vaporizer unit (1981).
- Livermore's involvement in magnetic fusion research dates from the founding of the laboratory in 1952. As lead laboratory for the National Magnetic Mirror Program, LLNL achieved thermonuclear plasma temperature with near-classical confinement in the 2X-IIB experiment (1978); demonstrated the adaptation of the mirror concept of an efficient reactor design in TMX (1980); and developed, with LBL large neutral high-field superconducting magnets Baseball II and Mirror Fusion Test Facility, MFTF (1981), which enhance related energy technologies like magnetohydrodynamics.
- Livermore has pioneered in underground engineering and experiments for weapons applications. Transfer to nonweapons applications includes rock fracturing for fossil energy applications and incorporating high-level radiation wastes in crystal lattices of synthetic rocks that are related to natural minerals with extremely long-period stability. In situ coal gasification was demonstrated in experiments at Hoe Creek, Wyoming (1979), that produced a medium BTU gas suitable for chemical synthesis or upgrading to pipeline quality. Industry has contributed resources to this effort.
- Beginning in 1972 and building on the foundation laid by LANL, LLNL has been a world-wide leader in the development of analytical cytology (flow cytometry, flow sorting, computer-based scanning microscopy, cytochemistry) and its application to energy-related toxicology. The laboratory has founded the new field of flow cytogenetics in which chromosomes are analyzed at high speed and resolution, and can, for the first time, be purified by type. LLNL researchers are also pioneering the application of analytical cytology to rare event detection, most noteworthy of which is the detection of somatic mutant cells in human blood. A practical assay for human somatic mutation would be a major breakthrough in the interface between preventive medicine and modern technological development.
- The Laboratory was also responsible for the development of the Atmospheric Release Advisory Capability (ARAC) System for predicting the exposure consequences from accidental releases of radioactivity with real-time communications to system sites. Conceptual studies were done in 1972; limited implementation occurred between 1974 and 1976; and the system was applied to the Three Mile

LAWRENCE LIVERMORE NATIONAL LABORATORY (Continued)

Island (TMI) accident and Kemeny Commission studies in 1979 and to the TMI Purge in 1980.

- Precision engineering and machining techniques for the design, fabrication,and inspection of highly precise mechanical workpieces have been under continual study and development since 1955. Two diamond turning machines were constructed (1968-72) for unprecedented accuracy in the machining of parts, and a third is in development. Assistance has been provided in transferring this technology to industry.
- A systems study of the aluminum-air power cell and its use in automotive propulsion, including performance, cost, and energy efficiency estimates was completed (1980). With industrial participation, the Laboratory is now developing and evaluating a prototype metal-air power cell as an automotive energy source with the range, acceleration, and rapid refueling capability of current internal-combustion engines.

LOS ALAMOS NATIONAL LABORATORY

Weapons

- Established in 1943, Los Alamos National Laboratory (LANL) developed the first fission and thermo-nuclear weapons. In conjunction with Sandia and LLNL, LANL has continued to maintain U.S. superiority in all facets of nuclear weapons technology and supporting scientific and engineering disciplines. Enhanced safety, flexibility, and military effectiveness have been produced through a reduction in size and weight of the weapons. These advances in design have enabled LANL to provide increasingly effective warhead capabilities for integration into a number of defense systems serving every branch of service.

Nonweapons

- Examples of major Los Alamos accomplishments before 1970 include designing, building, and operating the world's first plutonium-fueled fast reactor and the world's highest temperature and power density fission reactors, thereby establishing possibilities for advanced fission systems and eventual process heat applications. Los Alamos also achieved the first laboratory demonstration of controlled thermo-nuclear fusion, thereby establishing the possibility of eventual electricity production from fusion reactions.

- The Molecular Laser Isotope Separation (MLIS) Process for the enrichment of uranium has been developed to the point of demonstrating process feasibility. If developed to production scale, the MLIS process would result in a significant reduction in energy consumption and cost compared to diffusion and centrifuge technology. In response to the needs of the MLIS Program, state-of-the-art advances have been made in the area of laser research and development. The high-power, electric discharge excimer laser operating on all rare gas-halogen combinations has been successfully developed primarily at Los Alamos and by the Laboratory's direct contractors. In addition, LANL has pioneered the development of pulsed isotopic carbon dioxide lasers having long operating lifetimes and a high degree of stability. LANL contractors have produced the first high repetition rate, stable isotopic carbon dioxide lasers at the kilowatt/kilohertz level.

- Fast-reactor fuels of plutonium carbide developed by Los Alamos successfully attained specific power production (burnup) of over 150,000 mwd/ton(1981). This is much higher than that offered by present oxide fuels now used in breeder reactors. The new fuel has also demonstrated the capability of undergoing severe heating transients without performance degradation, an important safety feature. The combination of the improved thermal, mechanical, and neutronic performance of carbide fuel could lead to significant savings in fast-reactor fuel fabrication costs and in overall plant and operating costs as well.

- Special plutonium fuels using a Los Alamos oxide of ^{238}Pu and ^{18}O now provide long-life, stable, low background heat sources which generate electricity for experiments on the moon and on the Voyager spacecraft. Newly developed general purpose heat sources employing the same material will be combined in modular arrangements to power the Galileo Deep Space Probe and the Polar Orbiter solar studies mission. The same material, used in smaller radioactive heating units, has numerous space and terrestrial applications.

- Reactor transient codes designed by Los Alamos have been used to understand the behavior of complete nuclear reactor systems under accident conditions. These computational methods were successfully applied shortly after the Three Mile Island accident to reproduce that plant's behavior during the accident. Developments now under way suggest that this computational skill can be incorporated into high-speed microprocessor units at the power plants. This would give their operators rapid analysis during the course of a potential accident, guiding their response more surely to prevent the accident or reduce its consequences.

- The idea of extracting geothermal energy from structurally sound subterranean "hot dry rock" found nearly everywhere was conceived at Los Alamos eight years ago and has already had a first demonstration of technical feasibility. Heat transfer surfaces were created by fracturing the hot rock between deep drill holes and connecting the holes above ground to form the world's first closed loop geothermal energy system. This environmentally-clean recirculating system produced an average 2.0 megawatts (MW) of power for over 10,000 hours, and a portion of this was regularly used to generate onsite electricity up to 60 kilowatts (kw). Now, under joint sponsorship of the USDOE and the governments of West Ger-

many and Japan, a larger (35 MW) engineering system is being constructed (in 300°C rock at 4050 m depth) to demonstrate commercial feasibility. The project has already advanced that state-of-the-art in hard rock drilling has pioneered in deep drilling (two-three miles) at high temperatures. Many of the new high-temperature downhole tools and instruments developed for this work have already been adopted by industry. Prospecting techniques developed at the Laboratory are now being used to define and map the more readily accessible parts of this enormous nationwide resource.

- Flow cytometry, developed at Los Alamos, is automatic high-speed sorting of thousands of specific cells, chromosomes, etc., per second using laser illumination of individual cells to measure and select cell size, structure, and chemical composition (1972). This newly transferred technology is already worth several million dollars annually to industry. It is used in health research laboratories and is entering medical and clinical use. It is being applied to disease diagnosis and identification of genetic diseases and tumor cells; it is also being used to study the effects of radiation therapy, drugs, or toxic agents on cells and to develop chemotherapeutic cancer treatment schedules. An emerging application may make it possible to quantify the importance of chromosome aberrations as biological markers for chemical exposure (1972).

- Nonconventional hard materials are a very recent development that may replace tungsten carbide-cobalt in armor-piercing munitions, machine tool bits, mining drilll bits, and other applications where high hardness and abrasion resistance are important. These materials do not require strategic materials or cobalt and will use less tungsten. This development has both commercial and defense applications (1981).

- Accelerator developments at Los Alamos have found many practical applications. The mid-1960s discovery of the side-coupled cavity concept greatly increased the efficiency of transferring power to linear accelerator beams and is now adopted almost universally. Recently, LANL has learned how to apply the RF quadrupole bunching and guidance concept successfully to the low-velocity portions of ion linear accelerators. Essentially all such new machines are expected to adopt this technology as well. At the Los Alamos Meson Physics Facility (LAMPF), an accelerator which is nationally and internationally used, researchers have pioneered in the treatment of deep-seated human tumors by pion radiotherapy. Clinical successes and availability of the above technological improvements have encouraged the development of a compact machine especially optimized for hospital use. It is called PIGMI (Pion Generator for Medical Irradiations), and its design concepts are being shared with domestic companies and companies in Japan and Sweden.

- A program for the separation of isotopes of carbon, nitrogen, and oxygen (ICON/L/C) has produced kilogram-per-year quantities of ^{13}C, ^{15}N, ^{17}O, and ^{18}O. The unique 225-m long, cryogenic distillation column of this program is the major source of these isotopes in the Western world. The separated stable isotopes are utilized in physical and biomedical sciences and in environmental studies through basic research programs and extensive cooperative ventures with universities and medical schools.

OAK RIDGE NATIONAL LABORATORY

- Oak Ridge National Laboratory (ORNL) served for over 30 years as the principal developer and reference source for models and techniques to estimate radiation doses received by humans. Essentially all nations have uniformly adopted usage of the ORNL models and techniques through the recommendation of the International Commission on Radiological Protection (1940s to present).

- The Laboratory has developed advanced centrifuge techniques producing pure vaccines and for performing rapid medical diagnoses. These are now in wide-scale commercial use (1965-1975).

- The development of radionuclide production for nuclear medicine applications was initiated at ORNL, and, in conjunction with medical schools and hospitals, the Laboratory developed efficient radiopharmaceuticals as imaging agents to study heart disease and locate brain tumors (1945 to present).

- The first heavy-ion cyclotron was constructed at ORNL, and the field of heavy-ion physics was founded by establishing the general properties of heavy-ion elastic scattering, transfer reactions, and compound nuclear reactions (1950 to present).

- Crucial determinations were made of neutron radiation damage, including radiation-induced creep, in metals and alloys; contributions in this area have been necessary for the development of nuclear reactors (1949 to present).

- Theory and supporting data for the design of heavy section steel vessels were developed at ORNL. The results of this program have provided an assurance of safety necessary for the light-water reactor (LWR) pressure vessel, which has been accepted by regulatory bodies both in the United States and other countries (mid-1960s to present).

- The Laboratory provided rapid and extensive assistance during the Three Mile Island incident, from the beginning until now. Radiochemical, chemical, and isotopic measurements were made, along with a variety of physical tests. ORNL developed the process flowsheet for the cleanup of the water from the containment building. ORNL also resolved the question of why iodine releases were so low and showed that much lower iodine releases than previously predicted would occur in many LWR accident scenarios (1980 to present).

- For nuclear fuel reprocessing, ORNL developed Purex (1953), Thorex (1958),and Remotex (1980). Purex and Thorex processes are now used in all known fuel reprocessing plants throughout the world. Remotex is a fully remote processing concept which has been used for most radioisotope systems and also has been applied to the handling of hazardous materials such as carcinogenic compounds.

- The major contributions to the development and application of neutral injection heating for fusion were made at ORNL. These include the development of the initial physics and technology, as well as a prime contribution to the initial applications and understanding of this important plasma heating technique (1969 to present). Devices were also developed at ORNL which, in conjunction with the Princeton Plasma Physics Laboratory, produced a 70 million degree plasma in the Princeton Large Torus (1978).

- A broad array of instrumentation and monitoring techniques for fossil-energy-related applications was developed that provides the basis for work area monitoring for industrial hygiene purposes of a broad class of carcinogenic polyaromatic hydrocarbons (PAH) which are produced in coal conversion reactions. The instruments include the derivative ultraviolet absorption spectrometer (DUVAS) for detection of specific gaseous organic emissions, the portable "spill spotter" for detection and quantification of work surface PAH contamination, the light-pipe luminoscope for detection of PAHs on skin, and a personnel monitor for determining individual worker exposure to volatile organics, including PAHs (1977 to present).

PACIFIC NORTHWEST LABORATORY

- The Pacific Northwest Laboratory (PNL) successfully demonstrated the immobilization of high-level waste from the nuclear fuel reprocessing of six commerical fuel assemblies in a stable glass form for storage (1976-1979). The process is being transferred to the Savannah River Laboratory for use in the Defense Waste Processing Facility. It will be used in the West Valley Demonstration Project to solidify the liquid high-level wastes stored in tanks at the site.

- For over 30 years the Laboratory has conducted experimental research that has lead to major improvements in nuclear power plant and core fuel performance, core life, plant safety, and plant factors. This research has included a cooperative program (1973-1975) with Japan and several European countries that led to resolution of fuel densification questions threatening shutdown of numerous nuclear power plants in the United States and throughout the world.

- The Laboratory established the technical, health, and environmental basis for the private-sector use of mixed oxide (plutonium and uranium) fuels in light water reactors (1960-1970). The studies have led to a technology base for a better understanding of the use of uranium oxide and mixed oxide fuels. The technology was adopted by one corporation as a new venture of providing mixed oxide and uranium oxide fuels that has grown to a multihundred million dollar fuel reload business with a billion dollar backlog (1967-1975). Also, critical mass data for plutonium, uranium, and mixtures of the two provided information used by industry to design nuclear fuel cycle facilities and equipment (1967 to present).

- Electropolishing and vibratory-finishing techniques for decontaminating metal surfaces were developed at PNL. These techniques are being used for the cleanup at Three Mile Island; they have been incorporated in mobile decontamination units operated by seven commercial companies; and they are factored into decontamination plans of most DOE sites (1975-1980).

- An advanced cooling-tower process that used little or no water was developed; this is an important alternative for arid Western states and other regions of uncertain future water supply. The concept is being demonstrated by the private sector at a utility power station and holds the potential of 30% to 40% cost reductions over existing dry-cooling technology (1974-1981).

- High-rate and large-volume sputtering processes have been developed for the versatile fabrication of special-purpose materials and coatings. The technique has been used for coating turbine blades for increased reliability, fabricating materials for high-energy-laser mirrors, and trapping krypton gas in metals in order to meet release criteria for nuclear reactors and other nuclear facilities (1969 to present).

- Experiments on effluents and products for coal conversion processes conducted for about six years suggest that mutagenic and probably carcinogenic effects of coal liquids are due to a relatively small faction of the constitutents of coal conversion liquids. Mutagenic effects are due to primary aromatic amines. Also, researchers found that coal liquids, because of their high phenol content, are more toxic to aquatic organisms than petroleum and petroleum-based fuels. Hydrotreatment of the coal liquefaction materials reduces these toxic constituents and is expected to ameliorate effects. Results are being used by industry to (1) develop alternative coal conversion processes that produce less phenol and fewer primary aromatic amines, (2) modify processes to remove these mutagenic and toxic constituents, and (3) assess potential environmental and health impacts of a commerical coal liquefaction industry (1976-1981).

- The Laboratory has developed a cationic asphalt emulsion that can be used to seal radon gas in piles of uranium tailings. The new emulsion forms a tight electrostatic bond with the soil rather than the usual mechanical bond. Results after six months of a field study with the new emulsion indicate a greater than 99.99% reduction in the amount of radon gas normally released from uncovered tailings (1978-1981).

- Health and environmental studies of radionuclides have been conducted at Hanford for over 30 years using Hanford-developed instruments and procedures for low concentration measurements. Health effects of transuranic (radioactive) elements were measured as a function body entry route, specific radiation compound, and animal species and ages. Possible synergistic and antagonistic effects of combined exposures to transuranic elements and

57-279 O - 87 - 54

PACIFIC NORTHWEST LABORATORY (Continued)

nonnuclear environmental contaminants were determined. Effects of environmental exposure routes and mechanisms of biological availability of transuranic elements were also ascertained. These data are widely used in setting or justifying existing radiation exposure standards and as a basis for resolving issues and making decisions. For example, results from studies of plutonium have clarified questions about potential health effects of plutonium and the issue of "hot particles"; and results from krypton inhalation studies supported that decision to vent krypton gas at Three Mile Island (1977-1981). The extreme measurement sensitivities resulting from the instrumentation developments and radioanalytical procedures have been used for meteorite and lunar sample analysis, exploitation of mineral resources, nuclear proliferation control, and categorization and characterization of pollutants from all phases of energy production.

- The Laboratory has been instrumental in developing siting and methodology criteria in support of major national programs. In the 1960s, extensive environmental studies were conducted at both Cape Canaveral, Florida, and Vandenberg Air Force Base, California, which established criteria for safety in expanding space programs, including that required for siting of launch facilities. In the early 1970s, the response to new legal requirements for environmental assessment of commercial nuclear facilities, measurement and analysis methods were established to determine the health and environmental impact from nuclear operations. Criteria and procedures developed by PNL for environmental impact statements of nuclear reactors were rapidly deployed and are still used by industry. More recently (1977-1981), siting criteria, realistic wind data, and measurement techniques have been developed that facilitate the use of modern large and small wind turbines in the continental United States. Specific uses of the PNL information and techniques by the private sector include: (1) screening potential sites for power production units; (2) improving site selection capabilities; (3) conducting market studies, economic analysis, and feasibility studies; and (4) diversifying their business to include wind measurements (1962-1981).

SANDIA LABORATORIES

Weapons

- Since its establishment in 1949, Sandia has developed safe, reliable, deliverable, field-ready weapons using the nuclear devices developed by LANL and LLNL. Sandia's weapons research and development includes arming, fuzing, and firing systems; command and control systems; and the structural and aerodynamic designs. Significant advances in safety, security, and flexibility of those systems as well as in miniaturization of components and protection against hostile environments have been made. Sandia has also been instrumental in extending component shelf life, thus greatly reducing stock-pile maintenance costs. The Laboratory performs these functions for all nuclear weapons in the stockpile. Until about 1973, Sandia's activities were 100% defense related; today about 75% of the staff is engaged in defense activities. Since defense work is classified, representative unclassified examples of accomplishment cannot be supplied except for the nonweapon projects started within the last five-ten years.

Nonweapons

- In a program initiated in the early 1970s, Sandia has discovered a family of transparent electroptic ferroelectric ceramics based on lead lanthanum zirconate titanate (PLZT) and has developed unique solid-state devices based on these materials. The applications include image storage, processing, and display devices; light valves and shutters (e.g., flashblinders and welding goggles, spectral and variable density filters); and numeric displays. Over 20 companies and laboratories in the United States and abroad now have active research and development programs on PLZT materials and devices.

- After conducting systems studies of fossil and geothermal processes, Sandia developed more than two dozen devices and processes now widely used by industry. Examples are high-temperature microcircuits, coring devices, new drilling muds, new hardrock drill bits, and a downhole combustion device for injecting steam into oil-bearing formations. Since about 80% of this country's heavy oil deposits will be recovered using thermal energy, it is significant that downhole steam generators use less fuel, create less pollution, and recover more oil from greater depths than surface generators. Several commercial firms are in design and manufacture of the device (1974-1982).

- Sandia has managed a significant fraction of the national solar energy program. The Laboratory's systems studies and experience with costs of hardware construction and operation revealed market limitations that were not commonly recognized nor publicized. Over 20,000 industrial and political decision makers have been extensively briefed on the results of this work (1972 to present).

- Sandia's Combustion Research Facility was opened in 1981. Already, experimental results and computer codes from the combustion research program have been used by the automotive industry to modify engine designs for greater fuel efficiency, and theoretical analyses have enabled oil and power systems to devise a technique for significantly reducing a major pollutant product of combustion.

- In 1975 a patent was granted on Sandia's Hot Gas Solder Leveler, which, relative to other solder levelers, reduced process time by 90%, pollution by 95%, and power requirements by 60%. Several firms have manufactured the hundreds of Hot Gas Solder Levelers in use domestically and overseas; annual sales estimates are in the neighborhood of $20 million.

- Since the concept of using laminar airflow to create ultraclean and contamination-free environments was developed at Sandia in the early 1960s, numerous manufacturers have produced many thousands of clean rooms and work stations for medical, industrial, and other applications. Annual sales in the United States are estimated to exceed $100 million.

- Sandia has identified and developed understanding of very important long-term, low-level radiation damage dose-rate in polymeric materials used in nuclear power reactors (1978 to present). This work, which grew out of extensive radiation effects research, has resulted in the worldwide reexamination and rewriting of test methodology for qualification of materials used in nuclear power reactors.

- Experimental and analytical data that reduce the uncertainties in understanding several accidents in commercial nuclear power rectors have been developed here. The program uses Sandia's unique Annular Core Research Reactor (ACRR) as well as other specialized materials test

SANDIA LABORATORIES (Continued)

facilities. This program has shown several hypotheses used in designing for future reactors to be incorrect. Also, the ACRR has allowed reactor safety experiments that produce more accurate assessments of reactor safety (1975 to present).

- Sandia has developed the technology for radiation-tolerant large-scale integrated circuits and transferred this technology to industry. Radiation-hardened microelectronics applications include national security, nuclear reactor instrumentation, satellite based equipment, and the U.S. space program.
- New concepts and techniques in modular pulsed power, power conditioning, and power concentration that are leading to particle accelerators and similar devices capable of delivering extremely high energies and powers have been developed. These devices are finding important applications in studies of high-energy-density plasmas, the effects of intense radiation on materials, and directed-energy particle beams (1972 to present).

II. SUMMARY AND PERSPECTIVE

A. Mission, Goals, and Objectives

The Reagan Administration assumed office in January 1981 committed to maintaining U.S. leadership in aeronautics and space. Toward that objective, it gave top priority to completing development of NASA's Space Shuttle and, with the Shuttle as the core element, to achieving full operational status for the Space Transportation System as an economically profitable and productive national resource. Advancement of those and other NASA space programs has benefited the economy and, at the same time, confirmed NASA's status as a world leader in science and technology. Space exploration has been and continues to be a catalyst for national progress and achievement.

The direction of NASA's mission and activities in space continues to reflect national policy and purpose as stated in the National Aeronautics and Space Act of 1958, as amended. A landmark achievement of the U.S. political system, that act directs NASA to explore space for peaceful purposes for the benefit of all mankind and to cooperate with other nations or groups of nations in pursuit of the Act's objectives. The President reaffirmed that commitment in his State of the Union address to Congress on January 25, 1984. He presented "four great goals to keep America free and secure in the eighties": "to ensure steady economic growth," "to build on America's pioneer spirit and develop our next frontier--space," "strengthening our community of shared values," and "a lasting and meaningful peace."

On August 15, 1984, the President approved a National Space Strategy designed to implement the national policy for space, as amended by Congress and as supplemented by his State of the Union address. The provisions of that strategy applicable to the civil space program are to:

- Insure routine, cost-effective access to space with the Space Transportation System
- Establish a permanently manned presence in space
- Foster increased international cooperation in civil space activities
- Identify major long-range national goals for the civil space program
- Insure a vigorous and balanced program of civil scientific research and exploration in space
- Encourage commercial Expendable Launch Vehicle activities
- Stimulate private sector commercial space activities.

Development of the space frontier, the President's second goal, will affect, and contribute to achievement of, his other three goals; and the major new element in his strategy that will help to ensure meeting that goal is establishment of a permanently manned presence in space. Permanent manned presence in space will enable the Nation, he said, "to follow our dreams to

distant stars, living and working in space for peaceful, economic and scientific gain." The NASA program initiated to establish that permanent presence is the Space Station.

As currently perceived by NASA engineers and scientists, the Space Station will be evolutionary in concept and design to accommodate addition, modification, and in future decades, replication. It is to be a multipurpose facility in Earth orbit, permanently occupied by humans. A national research laboratory for both government and industry, it will serve, as well, as a repair and assembly station for satellites and space payloads. As it evolves, it ultimately will serve as a base for new operations and initiatives in space and, most important, will be valuable for the creation of new technologies and industries. Such a facility in full operation, the President pointed out, has "enormous potential for commerce." Research in space is expected to yield new products leading to new businesses. In addition, development and production of the Space Station will be a boost to the economy; and the new skills, advanced knowledge, and technology that result will be used in other areas of industry. Each new step in achieving aerospace goals has added new dimensions of excellence to industrial capabilities; and if past is prologue, this great enhancement of space capabilities certainly will contribute to economic growth.

Pioneering in space by building a permanent settlement in that vast frontier also has meaning with respect to the President's third and fourth goals: "strengthening our community of shared values" and "a lasting and meaningful peace." A community in space, with U.S. personnel working and functioning there, will reflect the shared values of a democracy in action for freedom and peace. The President intends the U.S. Space Station to be an instrument for peace. Other nations, he stated, will be invited to join the United States on the Station "so we can strengthen peace, build prosperity and expand freedom for all who share our goals."

Estimates are that the Space Station can be in orbit by the early 1990s, around the 500th anniversary year of America's discovery by Columbus. Now, as then, the discovery of a new frontier is prelude to its development. A new world emerged then; and mankind now may be on the threshold of building another new world or, at least, of extending Earth's limits into near space and beyond.

Support of the Space Station and of other anticipated activities will require definition, design, and acquisition of a second-generation space transportation system, including unmanned cargo vehicles and second-generation orbiters.

In extending Earth's limits, NASA has set for itself the following goals, each of which is in keeping with the mandates of the National Aeronautics and Space Act of 1958, as amended:

- Provide for our work force a creative environment and the best of facilities, support services, and management support so that they can perform with excellence NASA's research, development, mission, and operational responsibilities. Provide for the development of employees so as to enhance and sustain an integrated work force of highest quality at NASA.

- Make the Space Transportation System fully operational and cost effective in providing routine access to space for domestic and foreign, commercial, and Governmental users.

- Develop within a decade a permanenty manned Space Station.

- Conduct an effective and productive aeronautics research and development program which contributes materialiy to the enduring preeminence of U.S. civil and military aviation.

- Conduct an effective and productive Space and Earth Sciences Program which expands human knowledge of the Earth, its environment, the solar system, and the universe.

- Conduct effective and productive space applications and technology programs which contribute materially toward U.S. leadership and security.

- Expand opportunities for U.S. private sector investment and involvement in civil space and space-related activities.

- Establish NASA as a leader in the development and application of advanced technology and management practices which contribute to significant increases in both Agency and national productivity.

The Administration's proposed budget for NASA for FY 1986 supports those goals, including sufficient funding for some new initiatives. It reflects the President's commitment to establishing a permanently manned space station and recognizes the importance of research and development for the well-being of the national economy. Flight activity will continue to increase to accommodate not only NASA payloads, but also those of paying customers, with plans calling for 10 Shuttle flights in FY 1985, 14 in FY 1986, and continued increases through the end of the 1980s.

The principal activities provided for are as follows:

- Space Transportation--While moving forward on the Space Station program, top priority attention to achieving for the Space Transportation System the ability to fill space transportation needs through the 1980s and beyond

- Space Science and Applications--Continued progress on approved projects, initiation of such programs as Upper Atmosphere Research Satellite, and further technology development and ground test and flight test programs for the Advanced Communications Technology Satellite

- Space Research and Technology--Continued efforts in generic disciplinary base technology programs with modest expansion of system oriented efforts in platforms and Space Station technology, transportation systems, and spacecraft

- Aeronautical Research and Technology--Additional work in aeronautical disciplines such as aerodynamics, structures, materials, propulsion,

and controls to provide technology for totally new aircraft systems, including rotorcraft, high performance and subsonic aircraft, and advanced propulsion systems

- The Institution--Maintenance and improvement of NASA's professional work force of scientists, engineers, and technicians to ensure efficent, effective, and innovative progress in fulfilling program objectives.

B. Space Program Highlights to Year 2000

The subsections of this chapter that follow present the highlights of the programs NASA plans to conduct in the remaining years of the 20th century, including the programs' goals, objectives, and major new initiatives planned for the 10-year period beginning in FY 1986. Each program is described in greater detail in chapters III through IX of this report.

1. Space Science and Applications

The Space Science and Applications program is responsible for most of the Nation's scientific research in space and for exploring ways in which space can be used in practical applications by industry, in the life sciences, and in maintaining Earth's natural resources. It includes observations and studies of the distant universe and of the fundamental physical laws important to understanding the distant universe, exploration of the near universe, and efforts to understand more about Earth's planetary features and environment. Its applications programs include research in the life sciences to enable humans to function and work in space, experiments in materials processing in the microgravity of space, and expansion and improvement of such services as satellite communications.

Summaries of the six major areas of endeavor in space science and applications follow. Each area is described in greater detail in chapter III.

a. Study of the Distant Universe

As a result of NASA's program in space astronomy and astrophysics during the past two decades, a new view of the universe is emerging; and new discoveries are being made at an astonishing rate. Rocket and satellite observations at ultraviolet wavelengths reveal the ejection by many types of stars of enormous amounts of material at high velocities. A revolution is occurring in knowledge of the chemical composition and physical state of interstellar gas and dust. Entirely new types of celestial objects are being discovered. Explosive events of unimaginable violence that occur routinely in the universe are being observed. Studies of the sun, fundamental to interpreting the distant universe, may provide the first look into that star's interior. For assurance that this revolution in understanding of the universe will continue at the same rapid pace, new observing capabilities are planned.

In the current Astrophysics program, several research missions are providing diverse information and measurements on the nature of the universe. While each mission has a particular objective, the data it acquires may often be augmented substantially by data from one or more

other missions. For example, the objective of the Solar Maximum Mission is to observe solar flares, but data from several other missions add to understanding of flares on the sun and other stars.

The International Ultraviolet Explorer supplements the Solar Maximum Mission. The Space Telescope, scheduled for launch in 1986, is the first major astronomical observatory designed and built to be serviced and upgraded in orbit. It is planned to be in operation for two decades and will be able to make observations in the ultraviolet, visible, and infrared regions of the spectrum. The Infrared Astronomy Satellite was launched in 1983 in cooperation with the Netherlands and the United Kingdom. Analysis of its data continues to provide new discoveries in infrared astronomy. Under development and to be launched within this decade are the Roentgen Satellite, a cooperative program with the Federal Republic of Germany to investigate many phenomena discovered by the second High Energy Astronomy Observatory; the Gamma Ray Observatory, to investigate the highest energy reaches of the electromagnetic spectrum; the Cosmic Background Explorer, to measure precisely the spectral and directional distribution of cosmic microwave background radiation; and the Heavy Nuclei Collector, to detect charged particles such as the rare, heavy nuclei of uranium. The program also includes extensive theoretical and laboratory research and investigations to be flown on Spacelab.

The major initiative to be begun through FY 1990 is the Advanced X-Ray Astrophysics Facility, which will advance x-ray astronomy into the mature observatory stage. It will be as significant an advance in x-ray astronomy as the Space Telescope will be in optical astronomy. Other initiatives planned for the FY 1986 through FY 1990 period are principally investigations of the structure of space and time, the structure of the sun, the life cycle of stars and galaxies, and interstellar space. They include Gravity Probe-B, Space Infrared Telescope Facility, Solar Seismology Mission, Extreme Ultraviolet Explorer, X-Ray Timing Explorer, Far Ultraviolet Spectroscopy Explorer, Solar Corona Diagnostics Mission, and several Spacelab investigations.

In the period between FY 1991 and FY 1995, two mature observatories will enter development. The Advanced Solar Observatory will make coordinated observations of all aspects of the surface of the sun to study the evolution of solar features and observe events that are especially revealing. The Large Deployable Reflector will investigate the processes of birth of celestial bodies. Other planned initiatives are the High Throughput Mission, Very Long Baseline Radio Interferometry, and Starprobe. The Space Station will service those observatories during this "golden age" of astronomy.

b. Exploration of the Near Universe

The near universe includes all bodies in the solar system except the sun and Earth. Exploration of the near universe is vital to a full understanding of the relationship of Earth to the sun and other members of the solar system. Specific goals of the program are to understand the origin, evolution, and present state of the solar system; Earth through comparative planetary studies; and the relationship between the chemical and physical evolution of the solar system and the appearance of life.

In the years since the first flyby of Venus, planetary exploration has experienced a golden age. It has brought new knowledge and established U.S. leadership in this area of space science. U.S. spacecraft were the first to visit Mercury, Venus, and Mars. Only U.S. spacecraft have crossed the asteroid belt into the outer solar system; and only a U.S. spacecraft, Pioneer 10, has exited the solar system. All told, over two dozen bodies--planets and their satellites--have been explored at close range; and the interplanetary medium has been partially characterized.

The current solar system exploration program consists of three parts: planetary research and analysis, development flight projects, and mission operations and data analysis. Research and analysis and mission operations and data analysis ensure program continuity toward exploration goals. Flight projects currently progressing are the Voyager 2 extended mission, which is headed for encounters with Uranus in 1986 and Neptune in 1989, and continued operation of Pioneer Venus, Pioneers 6 through 11, Voyager 1, and the International Cometary Explorer (the retargeted International Sun Earth Explorer-3), which is on its way to an encounter with the comet Giacobini-Zinner in 1985. Approved flight projects in the pre-launch development stage include the ASTRO payload planned for flight on the Shuttle to observe Halley's Comet during its 1986 flight through the solar system; Galileo (Jupiter orbiter and probe), which is a cooperative project with Germany; International Solar Polar Mission, which is a cooperative project with the European Space Agency; the Venus Radar Mapper, the first of the moderate-cost missions recommended by the NASA Advisory Council's Solar System Exploration Committee; and the Mars Observer, the first of the Planetary Observers, to be launched in 1990 to investigate that planet's atmosphere, surface geochemistry, interior, and climate on a global scale.

The Solar System Exploration Committee has recommended a core program containing 13 exploration missions, including the Venus Radar Mapper and the Mars Observer, to be undertaken by the year 2000. In support of that program, four new initiatives are planned for the next five years. They will establish firmly the exploratory phase of exploration in all regions of the solar system. The first is the Comet Rendezvous and Asteroid Flyby, scheduled for launch in 1990. Its purpose will be to investigate the physical and chemical state of comets. The second is the Lunar Geoscience Observer scheduled for launch in 1991 to assess lunar resources and to extend the Apollo program's science investigations to a global scale. The third is Cassini (Saturn Orbiter and Titan Probe), to be launched in 1993 to investigate Saturn and the largest of its satellites, Titan, especially Titan's unique, dense atmosphere. The fourth is the Coma Atmospheric & Elemental Sampling and Return mission, whose objective will be to obtain both intact and plasmatized samples of comet coma materials and return them to Earth for detailed analysis.

The Committee also has recommended addition of one or more intensive study missions during the 1990s as resources then available permit. The core program was formulated under the constraint that no new enabling technologies be required for implementation. In contrast, the augmentation initiatives will require significant new enabling or strongly enhancing technologies.

c. Earth and Its Environment

The view of Earth from space has engendered a growing realization that a full understanding of Earth and its environment requires a strong global research program spanning the scientific disciplines associated with study of the whole Earth, including atmospheric physics and chemistry, oceanography, geology, geophysics, and the emerging science of the biosphere, global biology. NASA's program to study Earth is global, interdisciplinary, and integrated, with emphasis on understanding processes that affect Earth's habitability, particularly its biological productivity and air and water quality. The program involves coordinated observational, theoretical, and experimental investigations and development of future observing technologies. Those activities are complementary and together form a balanced program of system and process studies. The program consists of elements that range from the most fundamental Earth sciences studies from space, to experiments demonstrating how data from space concerning Earth's resources and environment can be used to benefit society.

The Earth resources part of the program uses multispectral (visible and near-infrared), thermal-infrared, and active-microwave remote sensing systems to collect data for research and to demonstrate the utility of remote sensing in agriculture, land-use analysis and planning, hydrology, and geology. Landsat spacecraft have been the principal vehicles for Earth resources observation. Landsat 4, launched in July 1982, carried the Thematic Mapper sensor into orbit for the first time. That sensor has about twice the spectral resolution, three times the spatial resolution, and four times the sensitivity of the Multispectral Scanner sensor carried by earlier Landsat spacecraft. Landsat 4 technical problems curtailed the sensor's operation; but Landsat D', launched in 1984, carries another Thematic Mapper. The Shuttle Imaging Radar-A and other experiments on the Shuttle also have provided much valuable and useful information. The current program includes experiments with an improved imaging radar system, SIR-B, which was first flown on the Shuttle in 1984.

The objective of the atmospheric science program is to increase understanding of atmospheric processes and their effects on weather, climate, and the global environment. The current program of observations to further that understanding uses sounding rockets; balloons; aircraft; free-flying satellites, such as the Earth Radiation Budget Experiment launched in 1984; and Shuttle-borne instruments. Programs are in process to study global biology, Earth's plasma envelope and its interaction with the sun, geodynamics, trace species in the troposphere, and the oceans.

Earth science programs planned for initiation by FY 1990 include the following: Shuttle-Spacelab Payloads--to study the basic processes by which electromagnetic energy and particle beams interact with plasmas in the universe and to acquire information on the behavior with time of the solar constant, the solar spectrum, and the upper atmosphere; Ocean Color Imager--to provide synoptic global measurements of chlorophyll concentration as a primary data base to which complementary ship, airplane, and buoy data can be added to yield primary productivity estimates of high accuracy for key oceanic regions; Tethered Satellite System--to develop with Italy a system to conduct Earth science and applications experiments in regions remote from the Shuttle; Topography Experiment for Ocean

Circulation--to improve significantly capabilities for observing the oceans on a global basis; Magnetic Field Satellite--to test results derived from Magsat-1 data and provide an updated survey for the 1990 reference field; Geopotential Research Mission--to provide the most accurate models yet available of the global gravity field, geoid, and crustal magnetic anomalies; and International Solar Terrestrial Physics Program--to attempt, for the first time, a quantitative study of the complete solar-geospace system.

Studies of Earth in the 1990s will focus on long-term physical, chemical, and biological trends and changes in the environment. They will assess the effects of natural and human activities and provide improved models for estimating the future effects of humans and other species on Earth's biological productivity and habitability. They will be interdisciplinary and require sophisticated supporting technologies, particularly for long-term data management.

d. Life Sciences

The Life Sciences program has two goals: to understand how life forms are affected by the environmental conditions they encounter in space and to find how life originated and evolved in the universe. Life in the universe is studied by basic research programs in exobiology--which considers the origin, evolution, and distribution of life and its chemical precursors, and in biospherics--which studies how biological processes interact with the global environment. The effects of space flight on humans are investigated in the biomedical research program, and a complementary gravitational biology program deals with effects on other life forms. All four of these programs pursue their objectives through combined ground-based research and experiments in space.

Applied work in the life sciences has the objectives of ensuring the health of spacecraft crews and of improving technology to support life and work in space. A medical program has been evolved to test operational countermeasures to mitigate undesirable effects of space flight and techniques for treating illness and injury in flight. Projects are conducted to develop technology for instrumentation, closed life support systems, spacecraft habitability, and simulation of human capabilities.

The current program includes extensive study of problems associated with maintaining the health and productivity of spacecraft crews, emphasizing particularly the Space Adaptation Syndrome that affects some crew members during the first few days of a mission, but also maintaining continuing emphasis on questions of cardiovascular deconditioning, bone demineralization, and other effects of long-term space flight. Also under study are the origin, evolution, and distribution of life and life-related molecules on Earth and elsewhere as part of the evolution of the cosmos; the effects of biological processes on global dynamics, including the atmosphere, oceans, and terrestrial ecosystems; and the effects of differing levels of gravitational force on Earth life forms. Both ground-based research and an extensive flight-experiment program are employed. These programs will be continued and augmented in the years ahead to ensure that the Life Sciences program's goals will be met. The activities associated both with the medical effects of space flight on

humans and with gravitational biology will be involved closely with the Space Station program through the next 15 years. The Space Station's operating plans call for flying a medically diverse population of government and private individuals routinely for periods as long as the longest Skylab mission, and also for unprecedented amounts of extravehicular activity. Although the health problems that will occur should not be serious, it will be necessary to compile data on what does happen to the individuals and to verify countermeasures and treatment methods.

The Space Station will be a permanent laboratory where medical and biological studies can last as long as necessary to understand fundamental questions and resolve uncertainties surrounding longer flights. During the 1990s, the Life Sciences program will investigate the physiological and environmental factors that set limits on the ultimate duration of flights with human crews. Also, basic research will be performed to identify specific mechanisms of gravity perception in plants and animals and to show how gravity affects the development of organisms. Technology programs will develop improved countermeasures, methods for definitive care of ill and injured patients, and life support systems that regenerate food as well as air and water for spacecraft crews.

A phased program in biospheric research, planned to begin in the 1980s and to continue through the 1990s, will use Space Station unmanned platforms carrying Earth-looking instruments. Its goal will be to acquire data for a comprehensive model of global biogeochemical processes, which will constitute a key element in understanding Earth as a system. The search for life will continue with expansion of data acquisition and processing capabilities for the Search for Extraterrestrial Intelligence program, and of the use of Space Station payloads to capture extraterrestrial dust and to analyze the organic material content of the dust.

e. Satellite Communications

NASA's role in developing technology for satellites and other components of space communications has been and continues to be one of providing leadership in support of the private sector communication satellite marketplace, flight testing communications satellite advanced technology involving risk beyond that which private companies are able to accept, and supporting government use of space in non-military communications projects.

NASA's Communications program is facing a new challenge in both the private and public sectors. Within only two decades of the launch of the commercial communications satellite, SYNCOM II, the orbital arc is approaching saturation, requiring NASA to develop new technologies involving beam-hopping antennas and on-board switching for new satellites that will make more efficient use of the orbital arc. In connection with public sector communications, the Space Station program requires development of technology for satellite-to-satellite links, giant antennas that can be assembled and tested in space, and geostationary platforms.

NASA's current program, developed with industry's help, consists of the following major activities:

- o Basic research and technology development to provide a technology base for all of NASA's communications programs, performed cooperatively by NASA, universities, and U.S. industry

- o Technical consultation and support services to ensure growth of existing satellite services and their incorporation into new satellite applications

- o Advanced technology development to provide new and expanded satellite services and experiment coordination, primarily in the public sector

- o Satellite-aided search and rescue, a cooperative program in which Canada, France, the Soviet Union, and the United States are developing and demonstrating a satellite system for detecting and locating the position of signals transmitted automatically from aircraft, ships, and individuals in distress

- o Development and flight test of the Advanced Communications Technology Satellite to investigate electronically-hopped antenna beam communications, on-board switching, spectrum conservation, and K_a-band circuits

- o Development, in cooperation with U.S. industry and the Federal Communications Commission, of technology and system architecture for a satellite system with large antennas to provide a communications capability to mobile users on Earth; and flight testing of the system in the 1990s

Possible major initiatives for the Communications program include the following:

- o Study and advanced development of communications for the Space Station complex, including tests of 30 GHz, 60 GHz, and optical frequency high and low data rate links (The links also may involve the Advanced Communications Technology Satellite, the Shuttle, and a dedicated Spartan free flyer.)

- o Development of an antenna assembly and test range, collocated with the Space Station, for testing satellites, antennas, and payloads before their commitment to flight or transfer to geostationary orbit

- o Development of giant antennas for use about 1998 by both scientific and commercial platforms assembled at the Space Station and then transferred to geostationary orbit.

f. Microgravity Science and Applications

The strong multidisciplinary base NASA has established in space materials science will be developed further through a vigorous flight program conducted with the cooperation of industry. The goals sought are to investigate the behavior of fluids and the effects on that behavior of

carrying out processes in the microgravity environment of space, to provide a better understanding of the effects and limitations imposed by gravity on processes carried out on Earth, and to evolve processes that exploit the unique character of the microgravity environment of space to produce results that cannot be obtained in unit gravity.

The current program consists of ground-based investigations, experiments in space on the Shuttle's mid-deck, and experiments in the Materials Experiment Assembly. Some of the ground-based investigations that promise valuable results are studies of the effects of convection in the growth of crystals, phase separation mechanisms other than gravity, containerless processing, and bioseparation processes. The two principal Shuttle mid-deck experiments that have yielded interesting results and are expected to be developed further are the Monodisperse Latex Reactor and Continuous Flow Electrophoresis. The Materials Experiment Assembly is a carrier for materials processing experiments that fills the experiments' support needs independent of the Shuttle's systems. Experiments that have been conducted in it include isothermal and gradient processing in general purpose furnaces, processing of monotectic alloys, growth of crystals from vapors, and processing in an acoustic levitator furnace.

The emphasis of the program during the next several years will be on crystal growth of electronic materials, solidification of alloys and composites, containerless melting and solidification, containerless formation of glass, separation processes, fluid and transport phenomena, and combustion processes in microgravity. Another important activity is development of materials research facilities and apparatus. Present emphasis is on Shuttle mid-deck facilities and apparatus that potentially can be upgraded to fly in the cargo bay or Spacelab and, later, on the space station.

Two functions of the Microgravity Science and Applications program will have a substantial effect on the possibilities for the program's commercialization: the use of space to obtain knowledge that can be applied to improve terrestrial processes and the processing of materials in space to take advantage of the weightless conditions there. For the near future, materials processing in space will be restricted to small quantities of high-value, low-volume materials such as pharmaceutical products, electronic materials, optical fibers, highly specialized alloys, and possibly precision latex microspheres. NASA will continue to conduct, with industry participation, a vigorous flight program to foster future ventures by industry that will be of optimum benefit with regard to both the materials produced and the economics of production. NASA sponsors, and encourages others to sponsor, materials processing research, but leaves to industry the task of deciding whether commercial production is feasible.

2. Space Flight

The Space Flight program supports NASA's goals for space transportation and a permanent presence in space. Its early goals are to develop the Space Transportation System further and achieve routine, economical operations with it. Planned programs emphasize development of follow-on systems for space transportation and other large space systems, including the Space Station,

orbital platforms and facilities, and the test, transportation, and servicing systems required to support them.

The program's objectives for the FY 1986 through 1990 period are to:

- o Complete development, acquisition, and upgrading to its full capability of the Space Transportation System, and achieve routine operations with it by 1988
- o Encourage use of the Space Transportation System by domestic and international commercial customers
- o Carry out a total of 30 Shuttle missions in FY 1985 and FY 1986
- o Develop by the second quarter of FY 1986 a cost-effective Centaur upper stage compatible with the Shuttle
- o Support and encourage commercial development of upper stages
- o Develop a tethered satellite system
- o Continue demonstration of the abilities of the Shuttle for servicing satellites
- o Develop by 1990 an Orbital Maneuvering Vehicle for use in conjunction with the Shuttle and, later, the Space Station.

The program's objectives beyond 1990 are to:

- o Maintain a Shuttle launch schedule with reserve capacity, while conducting safe, successful Shuttle missions having progressively lower operational costs and shorter turn-around times
- o Help in meeting NASA's objective of developing and putting into routine operation in low Earth orbit by the early 1990s a manned permanent space station facility
- o Develop an orbital transfer vehicle complementary to the Space Shuttle for transportation of payloads to, between, and beyond Earth orbits
- o Define, design, and provide a second-generation space transportation system, including unmanned cargo vehicles and second-generation orbiters
- o Develop and operate on a routine basis, beginning in the mid 1990s, geosynchronous orbit space platforms that are unmanned, permanent, and multifunction
- o Develop and put into routine operation by the year 2000 geosynchronous orbit facilities that are permanent, multifunction, and able to be periodically manned
- o Develop technology and techniques to construct, deploy, or assemble such facilities in space, and to test and service them in orbit

- o Encourage and support NASA and industry development of technology to improve concepts for space boosters that significantly reduce launch costs.

The objectives associated with bringing the Space Transportation System to full operation will be achieved through completion of the current base-line program. Most Earth-to-orbit and all return-to-Earth transportation needs will be met by the Shuttle, supported by the discrete Shuttle Production and Capability Development program. That program is responsible for Shuttle and propulsion system production and residual development, launch and mission support, and system improvements. Current activities are focused on the Inertial Upper Stage and the Centaur modified for Shuttle use; achieving full flight status for Spacelab; increasing opportunities for Spacelab-based science and applications work; operational support services for the Shuttle and expendable launch vehicles; and procurement of expendable items for both launch systems.

Proposed new initiatives support both the nearer-term objectives of space transportation operations and the longer-term objective to establish a permanent presence in space. During the period of this plan, capabilities for providing orbital services will be demonstrated. System hardware development will follow the demonstrations. The results of those demonstrations and the Tethered Satellite System program will help determine the limits of orbital activities of both the Shuttle and the Space Station.

NASA's inhouse institutional base and system of industrial and other contractors required to achieve the goals of the Space Flight program will be maintained and strengthened.

3. Space Station

Establishment of a permanent manned presence in space is one of NASA's current eight goals and is a priority goal of the Administration as a means of maintaining U.S. leadership in space and of exploiting the economic and scientific benefits in that new frontier. Toward that goal, the President has committed to development of a space station by the early 1990s.

The program's near objectives have centered on identifying and synthesizing mission requirements for a civilian space station and reviewing a set of functional capabilities--the station's architecture. In addition, technology and advanced development programs are being initiated. To meet the goal of initial operation in the early 1990s, current plans include a 3-year definition phase and initiation, in FY 1987, of a design and development phase.

Because many aspects of the program will make it unique as compared with past space programs, the following program and management strategies have been established:

- o All major potential users of the Space Station, U.S. and foreign, will be involved from the beginning of planning activities to ensure that their needs are taken into consideration.

- Thorough project definition will be conducted before system development is undertaken.

- Involvement in the program will be agency wide and substantive. Overall direction of the program is the responsibilty of the recently established Office of Space Station in NASA Headquarters. Johnson Space Center has been designated "lead center," responsible for NASA-wide program management of design, system engineering and integration, advanced development and test, and customer interface. Johnson and other NASA centers are responsible for project management of the development (by contractors) of system elements.

- The station will be designed to accommodate evolutionary growth through incremental addition, modification, and replication.

- The station's elements will be maintainable and restorable in space.

- A rigorous design-to-cost approach will be followed to keep design and development costs within the $8 billion currently estimated. The program definition phase will fully explore the necessary tradeoffs.

- International participation in the program will be sought. Participation will be on a government-to-govennment basis and be designed to prevent unwarranted technology transfer.

- Although the Department of Defense has not yet identified current military requirements for a space station, NASA will keep the Department fully informed of Space Station activities.

- The Space Station will be designed to operate as autonomously as possible, except for resupply of materiel and personnel. A major objective of current planning is to define the optimum mix of human and machine functions.

During its existence from 1982 through 1984, the Space Station Task Force focused almost exclusively on mission requirements for the Space Station. Based on the results of contracted studies and workshops with wide participation of potential users, a preliminary set of phased Space Station missions for the period 1991 to 2000 was defined. The initial requirements included a manned element at 28.5^{o} orbital inclination, a platform at low inclination, and a platform in polar orbit. Although no approved configuration exists, the present reference configuration calls for functional capabilities corresponding to two habitat modules, a logistics module, two laboratory modules, an unmanned platform at orbital inclination of 28.5^{o}, an unmanned platform at orbital inclination of 90^{o}, an Orbital Manuevering Vehicle, and a servicing system.

The Space Station program currently is concentrating on selecting contractors for program definition and preliminary design (to extend through 1986) and on advancing critical subsystem technologies; encouraging further international cooperation and planning; completing focused studies on human productivity, automation and robotics, and data management systems; completing development of a separate acquisition plan for a technical and management

information system; and continuing the progressive updating of Space Station functional requirements.

A Space Station advanced development program has been planned to provide advanced technologies needed for an evolutionary station. It will be integrated with system definition activities, with a major milestone and decision point occurring at the end of the definition phase. Both ground-based and space-based test beds are planned and are expected to have a vital role in subsequent definition of evolutionary elements. They are expected to reduce the program's costs and risks.

4. Space Tracking and Data Systems

The Space Tracking and Data Systems program supports the Nation's missions in aeronautics and space by planning for, developing, and operating the space and ground network of tracking and data systems for missions of automated and manned orbital spacecraft, deep space vehicles, sounding rockets, balloons, and research aircraft. The program has four basic elements: space network, ground networks, communications and data systems, and development of advanced systems. Plans for those elements and for supporting mission activities follow.

a. Space Network

By 1986, tracking and data acquisition facilities for spacecraft in near Earth orbit will have evolved from a network of ground tracking stations around the world into a network of two Tracking and Data Relay Satellite System (TDRSS) satellites in geostationary orbit, an in-orbit spare, and a single ground terminal at White Sands, New Mexico, all owned and operated by a contractor. A network control center at Goddard Space Flight Center will control the system and manage network resources. The system will increase coverage of near Earth orbits from 15 percent to 85 percent.

b. Ground Networks

NASA will close nine more ground stations while phasing TDRSS into operation, leaving only six locations fully operational and consolidated under Jet Propulsion Laboratory management. The consolidated ground network will support deep-space missions and missions in high Earth and geostationary orbits. Early improvements planned for the network include arraying antennas to boost the signal received from the Voyager 2 spacecraft when it is close to the planet Uranus and nearly three billion kilometers from Earth in 1986; adding an X-band uplink command system to the ground network about 1987 to reduce the blackout effects of the solar corona on signals from Galileo and later planetary missions, to improve signal stability by a factor of five, and to improve ability to search for gravity waves; developing a capability at Dryden Flight Research Facility for supporting multiple missions; providing tracking and data acquisition support to the National Scientific Balloon Facility at Palestine, Texas; and improving the impact prediction system and fixed radar capabilities at Wallops Flight Facility.

c. Communications and Data Systems

To handle the substantial increase in data transfer and processing that TDRSS services will generate, greater use will be made of electronic data transfer and other automated features to reduce the need for human intervention and tape handling. Aged and obsolete computing systems for mission support will be replaced to increase reliability and reduce maintenance costs; and more use will be made of microprocessors to control dish-antenna operations. By 1986 a program-support communications network will be in operation to provide NASA and its contractors with supplemental communications service for conducting day-to-day business.

d. Research and Development for Advanced Systems

Though relatively small, the Advanced Systems program is a vital part of the total program, providing a base for future planning and for development of cost-effective support capabilities. Its objectives are to increase abilities for communicating with spacecraft, improve navigation capabilities, increase the operational capabilities of ground stations and data handling and processing networks, and develop technology to facilitate TDRSS use.

e. Advanced Studies

The TDRSS is expected to meet needs through most of the 1990s, but increases in data volume for missions planned after the 1990s will require new relay capabilities. More links and greater capacity will be needed. Studies already have examined some support needs and new technology that may satisfy them. Other studies are in process on technological problems related to a follow-on system for the TDRSS.

Rapid advances being made in telecommunications technology will have a profound effect on tracking and data acquisition support of deep space missions in the coming decades by making possible, for example, a deep space relay station. The program will continue to look ahead and make plans to meet such challenges.

5. Space Research and Technology

This program is responsible for conducting space research and technology to support the Nation's civil and defense space programs and overall economic growth. It is concerned with technology with broad applicability rather than that related directly to specific projects; and it concentrates on long-term, high-risk research and technology development to satisfy national space objectives. With commercial and military investments in the use of space growing rapidly, the program is focusing increasingly on national objectives and missions and addressing the technology needs of those other sectors more directly. Much of the work constituting the program is planned in consultation with the other NASA program offices, the Department of Defense, and industry. Much also is conducted jointly with them to facilitate transfer to them of the technology developed.

The following objectives form the basis for the program and related institutional plans:

- To ensure timely provision of new concepts and advanced technologies
- To support the development of NASA missions in space and the space activities of industry and other government agencies
- To utilize the strengths of universities in conducting the NASA Space Research and Technology program
- To maintain NASA's centers in positions of strength in critical space technology areas.

Those objectives will be realized, as the objectives of the Aeronautics Research and Technology program are, through a program of disciplinary research combined with a program of systems research and technology development; enhancement of the staff, facilities, and computational capabilities of the NASA centers; increased and more productive involvement of the universities; and greater emphasis on favorable transfer of technology. Also, NASA will use and make available for use by others its unique resource of space facilities to conduct research and technology development in the actual space environment.

The disciplinary research and the systems research and technology development both concentrate on maintaining excellence in five priority technical areas: large, flexible structures and their control; space power systems; launch vehicle and space propulsion systems; entry technologies; and space operations. The disciplinary research further concentrates on aerothermodynamics, materials and structures, information sciences, space data and communications, controls and guidance, human factors, space energy conversion, and propulsion. The systems research and technology development further concentrates on space transportation systems, spacecraft systems, and large space systems. The two programs have common technology objectives that provide a basis for decisions on funding, personnel, and facilities. Those objectives are for materials and concepts for thermal protection; longer-life, reusable engines; propulsion and aerobraking for the Orbital Transfer Vehicle; high-capacity electrical power generation, storage, and distribution systems; satellite communications; large antenna systems; space teleoperation, robotics, and autonomous systems; space information management systems; computer science for aerospace applications; computational aerothermodynamic techniques for entry bodies and rocket engines; human capabilities in space; concepts for advanced sensors; and distributed, adaptive controls for large space systems.

Augmentation in FY 1986 is planned for the automation and robotics program, to provide technology to increase the capabilities of systems and the productivity of humans in space; the large space structures program, to provide technology for the control of large flexible structures in space; and the Orbital Transfer Vehicle program, to develop technologies for a space-based, reusable Orbital Transfer Vehicle. Augmentation planned for later years include increases for Orbital Transfer Vehicle technologies, automation and robotics, in-space experiments, enabling technologies, entry research vehicles, a liquid oxygen-hydrocarbon research engine, Mars sample return technologies, and lunar base technologies.

C. A Vision of the Space Era Beyond the Year 2000

Most of the programs described in this report of NASA planning will reach fruition by the end of the 20th century. With the beginning of the next century only 15 years away, it is none too soon to begin preliminary planning of possible systems, programs, and activities for the early years of the 21st century. Detailed planning would be premature, but a range of studies of possible alternative programs must be conducted to help set goals and objectives for that period, to identify programs providing the greatest potential, and to identify technologies that need to be pursued. The results of many such preliminary studies conducted in the past 20 years and others now under way have contributed to the material sketched below.

1. Space Infrastructure by the Year 2000

With the Administration's recent commitment to development of a permanently manned space station to be in orbit in the early 1990s, a significant orbital infrastructure should be in place by the year 2000 to support programs in science and exploration, development of technologies and their application to improve life on Earth, and a wide range of commercial activities. By the end of the present century, the permanently manned Space Station and associated unmanned platforms will have had some years of operation in low Earth orbit conducting many of those activities. Other supporting systems will have been developed, or will be within NASA's capability to provide. They will have the ability to support large, permanent facilities for science, research and development, commerce, and other activities in low Earth orbit and geosynchronous Earth orbit; to provide routine, economical, flexible access to other orbits by manned and robotic systems; to institute routine check-out, refueling, repairing, and upgrading of space facilities, as well as removal of Earth-orbital debris; and to devise and implement uses and missions for the Space Transportation System such as large tethered systems for power generation, nonpropulsive transportation, and satellite constellations.

A cryogenic version of the Orbital Transfer Vehicle evolutionary family, currently in early stages of preliminary design, is expected to provide by the year 2000 reusability for manned sortie flights to at least geosynchronous orbit. It also should be able to provide the basis for transportation for longer flights to establish a lunar base and for planetary missions such as a Mars sample return. Supplemented at times by a remotely controlled Orbital Maneuvering Vehicle with special kits for remote servicing, fueling, and debris capture, it probably should be able to fly with or without crews with minimum change. Because it appears that servicing, maintaining, and refueling those reusable vehicles will be more advantageously accomplished in orbit than on the ground, the Space Station must be equipped with suitable hangar, servicing, and refueling facilities.

A potential need exists for routine flights of unmanned, cargo carrying, Earth to low orbit vehicles that, compared with the Space Shuttle, will have the ability to accept payloads with larger diameters and to lift greater weights. Those Shuttle-derived launch vehicles would be available, of course, for the payloads of other users.

Various advanced systems, tools, and techniques will have to be available by the year 2000 for routine servicing operations in the space regimes

occupied by satellites and other spacecraft. Also, substantial augmentations to crew and life support systems will have to be developed. Those augmentations must provide closed-cycle, regenerative water and air loops for onboard environment control and life support systems; regenerable, space-maintained, life support backpack systems for extravehicular activity; high-productivity mobility systems; Earth-norm food, hygiene, and habitability; and onboard automation that is able to handle tasks that do not necessarily require continuous manned attendance and that is flexible enough to allow easy upgrading as technologies advance rapidly.

2. Space Programs of the Early 21st Century

For the United States to exercise leadership in space and to improve the well-being of humankind on Earth and in space beyond the year 2000, long-range goals will be required for advancing scientific knowledge, space exploration, Earth applications, and commercial uses. Those goals will be set by the Administration and Congress after consideration by many individuals and organizations, the National Commission on Space, NASA, and other groups involved in the U.S. space program. Sustained space research and development also will be necessary to conceive and develop even more advanced innovative systems and techniques than those that have been developed or will be developed by the end of this century. Concepts exist for major manned and automated space missions for achieving those goals and for providing unprecedented scientific and technical benefits. Those missions will use all regimes of space accessible in the early 21st century: low Earth orbit; higher energy Earth orbits, including geostationary orbit; lunar orbit; the lunar surface; and the environs of the inner planets.

Achievements in the early 21st century in science, exploration, Earth applications, and commercial uses will depend on two trends: first, the increasing capabilities of space systems with regard to accessibility, payloads, stay times, and variety and sophistication of operations and, second, the increasing capabilities of instruments with regard to detection, resolution, pointing accuracy, and data collection and management made possible partly by improvement of their power supplies and cooling mechanisms. Those trends and the space infrastructure they produce, such as the Space Station, will support scientific, technical, and commercial activities and systems not now possible, including:

- Large facility-class observatory instruments in both low Earth orbit and geosynchronous Earth orbit
- Orbital platforms, both equatorial and polar and both automated and human-tended, carrying instrument payloads that are modular, variable, serviceable, and interchangeable
- Large facilities such as telescope mirrors and radio antennas assembled in space by humans for both scientific and communications purposes
- Routine use of the lunar surface for planetary geoscience studies, solar monitoring, astronomical surveys, and possibly extraction of resources

- Routine materials processing in microgravity, at bench-test through pilot-plant levels, probably with extensive commercial involvement and continual increases in the variety and quantities of materials produced profitably on a commercial basis

- Significant increases in the number of humans present in space, in various Earth orbits and possibly on the lunar surface

- Large-payload, high-performance planetary exploration missions made possible by clustering launch stages or by using Orbital Transfer Vehicle derivatives

- Planetary science networks and other long-term activities on other celestial bodies such as the moon, Mars, and asteroids.

a. Earth Observations and the Near-Space Environment

NASA's activities in the 21st century will use the Space Station and its platforms to emphasize synoptic, continuous, and long-term observations of Earth and its immediate surroundings from both polar and equatorial low Earth orbits. A wide variety of multispectral, microwave, and other forms of sensors will provide critical global information about Earth's land surfaces, atmosphere, and ocean systems. A complementary system of sensors will collect data on the near-Earth space environment and its dynamic behavior by monitoring the sun, sampling and analyzing the solar wind, detecting solar flare particles, and studying Earth's magnetosphere and its interactions with solar activity.

As space transportation capabilities increase, similar platforms in geostationary orbit will provide continuous monitoring of larger areas of Earth. Also, automated or human-tended instruments located on the lunar surface will begin complementary observations. That location will permit observation of Earth's entire face, with simultaneous investigation of Earth's space environment and magnetotail.

The complexity of the scientific problems involved in studying Earth and its space environment, the variety of observations possible, and the potentially high rates of data collection will require major advances in ground-based data collection, management, and analysis and in modeling and prediction techniques. Also, mechanisms will have been developed for the creation and management of large, integrated, interdisciplinary projects like the current Global Habitability study.

b. Solar System Exploration

Exploration of the solar system will be carried out in several ways, using a variety of space capabilities. Even by the beginning of the 21st century, many relatively small, cost-effective missions contained in the Solar System Exploration Committee's recommended core program will remain to be conducted. They can be carried out with the Shuttle-Centaur combination, an equivalent transportation system as a straightforward continuation of NASA's 1980s and 1990s program, or new transportation systems utilizing the Space Station's facilities. Some more demanding

missions, such as the return to Earth of samples from Mars or a comet, can be carried out in a similar fashion.

Instruments, chiefly telescopes, for planetary studies will be mounted on and supported by the Space Station and its associated platforms. Even more significant, perhaps, the Space Station's fueling and launching capabilities and the availability of launch stages with higher performance will permit automated missions to planetary systems that now are not easily accessible. Examples of those missions are a Mercury orbiter, a Neptune orbiter and probe, intensive study of the Jupiter and Saturn systems, and sample return missions of greater sophistication.

Routine access to the lunar surface will make possible the first intensive, systematic study of another major celestial body. Extensive sample collection and scientific traverses conducted by humans and long-term instrument networks installed and managed by humans will help determine the details of the moon's structure, composition, and history. They also will make accessible the record of solar and cosmic ray particle fluxes preserved in the lunar soil. Similar scientific activities can be carried out on Mars, either by large, automated spacecraft or by a manned mission. Other scientific achievements will include orbital remote sensing of that planet and a rendezvous mission to its moons Phobos and Deimos to emplace instruments on and return samples from them.

c. Astrophysics and Solar Studies

Studies of the universe beyond the solar system will continue to depend on the Shuttle or its equivalent to place into low Earth orbit a mixture of small specialized missions and large observatory-class facilities similar to those studied for the 1990s by the National Research Council's Astronomy Survey Committee. Those missions and facilities will be structured to attack specific problems that remain as the new century begins.

Automated and human-tended platforms in the Space Station system will use a variety of astronomical instruments to conduct a wide assortment of complementary activities. The ability of humans to assemble large structures in space will make possible space-based astronomical instruments not limited by the size and weight constraints of a Shuttle payload; for example, large optical and infrared mirrors and large antennas for radio astronomy. The Space Station also will make possible an exciting program of studies combining observations and spacecraft missions to investigate the sun as a star. The Space Station will support the larger and more sophisticated instruments needed for observing and monitoring the sun; and high-performance launch stages such as clustered Centaurs or Orbital Transfer Vehicle derivatives will make possible solar probes, grazers, and orbiters.

The lunar surface will become available as a platform for astronomical observations. Initial studies will be made with small, prototype, human-tended instruments and will emphasize sky surveys and the detection of unpredictable events like supernovas and gamma-ray bursts.

d. Life Sciences

The first quarter of the 21st century will see a major effort to develop protective systems and physiological countermeasures to qualify humans for space flight missions years in duration. A group of dedicated Space Station modules will provide space laboratory capabilities for this work. Among the most serious problems to be solved are bone demineralization, loss of muscle mass, and radiation protection. Concurrently, operations and life sciences studies in a lunar surface base can develop the information required to plan for human residence on other planets. Around the turn of the century, practical controlled ecological life support systems will enable human habitations to operate with little or no requirement for external supplies of crew support consumables. Therefore, the essential medical and biological requirements for manned missions to destinations far from Earth should be in hand by 2025.

Basic research on gravity effects in living organisms will become an established specialty within medical and biological science, building on the results of the 1990s.

The search for extraterrestrial life will be pursued through the use of large radio telescopes installed in space that will have improved signal analysis capabilities.

e. Materials Processing

Even before the end of this century, materials production in the microgravity of space should have become routine, probably with extensive commercial involvement, for such diverse items as pharmaceuticals, crystals, alloys, and special glasses. Evolution of the Space Station will allow that activity to expand, possibly to the pilot-plant level or beyond, into separate laboratory modules and human-tended laboratories in low Earth orbit.

A variety of space-based power systems, including solar photovoltaic, nuclear, and solar thermal systems, will be essential. They will supply power to the growing industrial complex associated with the Space Station and, perhaps, to facilities in geosynchronous orbit. The program for developing and testing solar power systems also can explore the feasibility of transmitting power to, for example, Earth's surface or the moon.

Access to the lunar surface will make possible the first routine use of extraterrestrial resources. Techniques could be developed to enable a lunar base, even before its permanent occupancy, to mine, extract, and fabricate products from lunar materials. The objectives will be to make the lunar base able to support itself as much as possible from lunar feedstocks and to foster the economic use of lunar resources elsewhere in space (for example, the use of lunar oxygen by space systems in low Earth orbit). Extraterrestrial resources also will be investigated by means of missions, manned or unmanned, to near-Earth asteroids to obtain information on and assess the availability of resources, especially the essential volatile elements carbon, hydrogen, and nitrogen, that are lacking on the moon.

f. Communications

Drastically expanded communications capabilities will be needed in the early 21st century to support both scientific and commercial activities in space. That need will be satisfied mainly by large (10- to 100-meter diameter) antennas--assembled and tended in space by humans at the Space Station and located at geosynchronous orbit. Initiation of long-term human activities on the moon will generate a high demand for communications that will require lunar communications systems consisting both of networks based on the moon's surface and of lunar satellites acting as relays. Satisfying those communications needs will require not only extensive research, but also development of new systems--such as large, space-based antenna arrays--and of space-based storage and assembly techniques. New techniques also will be needed for handling the voluminous communications traffic generated by both scientific and commercial activities.

The space capabilities available after the turn of the century will create a revolution in space research, exploration, and exploitation. The resulting research and operations environment will have a potential that can be imagined only dimly at this time because of the many factors affecting that environment: large payloads; long instrument lifetimes; human-supported space operations; and routine access to low and geosynchronous Earth orbits, the lunar surface, and possibly the Martian surface and, for unmanned missions, the entire solar system. The inevitability of human exploration--and eventually habitation--of the solar system will begin to be apparent, and possibilities for tapping the resources of the moon and the asteroids will become evident. Means developed before the turn of the century for effectively monitoring Earth's environment will help humankind manage that environment wisely for the benefit of all. Use of space for industrial processes and other commercial purposes should be commonplace. Consequently, the early 21st century should be an era of unparalleled achievement for humanity.

D. Aeronautics Program Highlights to Year 2000

Upon completion of the Aeronautics Policy Study in 1982 by the Office of Science and Technology Policy, the Administration declared as a national policy objective the "provision of a proven technology base to support the future development of superior U.S. aircraft." That policy is sustained and, indeed, reinforced by NASA's goal for its Aeronautics program for FY 1986 and beyond: to conduct research and technology development that ensures the enduring preeminence of U.S. aviation. That goal is supported by the following program objectives:

- Maintain the excellence of the NASA research centers in facilities, computational capability, and technical and professional staff. This objective requires repairing and replacing aging facilities as well as developing additions and improvements, advancing scientific and engineering computational instruments and programs, and enhancing staff competence by selecting personnel with highest abilities and providing them with career incentives.

- Conduct disciplinary and systems research critical to the continued superiority of U.S. aircraft. Systems integration requires that

technical disciplines, usually treated in isolation at the basic level, be interrelated through systems research.

- Ensure the timely transition of research results to the U.S. aerospace community. For efficient, timely transfer of technologies to industry, increased attention must be given to active participation of industry in NASA's research and technology development through contractual and joint programs; timely dissemination of results through workshops, conferences, and reports; and dissemination to industry of information on technology advances made outside the United States.

- Ensure the involvement of universities and industry in NASA's Aeronautics program. NASA grants and contracts are an incentive to academic expertise in the university community and encourage technology development by industry for incorporation into new vehicle designs.

- Provide development support to the aeronautics activities of other government agencies and U.S. industry. While furnishing that service, NASA gains data and experience of benefit to its primary mission of aeronautical research and technology development.

Decisions on funding, personnel, and facilities for the program must be consistent with the program's long-term technology development objectives, which would:

- Bring external and internal computational fluid dynamics to a state of practical application for aircraft and engine design

- Significantly reduce aircraft viscous drag over the full speed range and improve understanding of Reynolds number effects at transonic speeds

- Through the use of advanced materials, minimize the structural weight of civil and military aircraft engines and airframes

- Provide advanced control, guidance, and flight management systems to improve performance and operation of future aircraft

- Increase by 100 percent the productivity and reliability of rotorcraft for military and civil application

- Ensure the availability of technology for superior military aircraft and missile systems

- Enhance flight crew effectiveness in advanced cockpit and air traffic environments that include advanced automation, display, and control techniques

- Exploit modern computers in solving computationally intensive aeronautical problems

- Exploit the full potential of techniques for enhanced performance through highly integrated propulsion-airframe systems

- Advance the technology for small gas turbine engines to a level comparable with that for large turbine engines
- Establish the technical feasibility of high-speed turboprop propulsion
- Advance enabling technologies for subsonic transport engines to improve their fuel efficiency and durability
- Increase aviation safety by improving crash and fire worthiness, protection from weather hazards, and aircraft systems.

The program will continue efforts both in basic aeronautical disciplines and in systems research and technology development. The principal areas of technology currently being pursued include: fluid and thermal physics--high Reynolds number cryogenic testing, viscous drag reduction, vortex flows, and computation of the aerodynamics of complex aircraft configurations; materials and structures--light alloy metals, new composite materials, and the crash dynamics of composite structures; controls, guidance, and human factors--aircraft with highly augmented controls, fault-tolerant systems, advanced automation of crew stations, and improved simulation; computer science--concurrent processing architectures, algorithms, and techniques for computational physics research; propulsion--advanced turboprop, small turbine engine, and general aviation and commuter aircraft engine technology; rotorcraft--noise and vibration reduction and unsteady rotor aerodynamics; high-performance aircraft--high angle-of-attack flight, vectored-thrust and short-takeoff-and-vertical-landing aircraft, maneuverable supersonic cruise aircraft, propulsion-airframe integration, increased engine performance and durability through the turbine engine hot section technology program, and hypersonic propulsion, structures, and configuration aerodynamics; and subsonic aircraft--icing and lightning research, natural and controlled laminar flow, and, in coordination with the Federal Aviation Administration, air safety, operations problems, and interfacing with the Air Traffic Control System.

Technical progress during the past year has permitted acceleration of work on advanced turboprops and oblique wings. In an effort to initiate a full-scale flight test of the Advanced Turboprop propulsion concept by 1987, NASA has augmented the Advanced Turboprop work dedicated to the flight test. Work in the oblique wing program now is directed toward flight demonstration and validation tests of the use of oblique wings at transonic and supersonic speeds.

Planned initiatives include development of technology in the following areas to respond to technical opportunities and needs and to satisfy the long-term technology development objectives listed previously:

- High-speed (hypersonic) flight--to provide a proven technology base for future options in aeronautics and space in the critical areas of air-breathing propulsion, aerothermodynamics, materials, structures, and system analysis, including the development of a recoverable hypersonic research aircraft
- Supersonic cruise--to obtain long distance efficiency for future military and civil aircraft

- o Computational fluid dynamics--to facilitate development of focused applications of computational fluid dynamics for important 3-dimensional viscous-dominated flows and development of pathfinding simulations of the fundamental physics of unsteady flows; to initiate development of techniques for performing integrated multidisciplinary analyses; and to apply expert systems to automating development of computational fluid dynamics analyses

- o Rotorcraft systems noise and vibration--to develop design methodology for future helicopters that will be acceptable to the community, have low vibration, and without sacrificing vehicle performance, have low acoustic detectability (for military applications)

- o Advanced fighter aircraft--to accelerate and integrate key enabling technologies, such as those for high thrust-to-weight propulsion, thrust vectoring for control, and high-angle-of-attack flight dynamics, for revolutionary advances in fighter capabilities

- o Transport aircraft laminar flow--to provide flight verification of a hybrid wing concept employing active laminar flow control in leading edges for a new generation of fuel efficient civil and military transports

- o Small-engine components--to provide major improvements in the fuel consumption, weight, reliability, and durability of small turbine engines for a broad range of future military and civil applications

- o Superaugmented rotorcraft--to achieve an all-weather operational capability for a single-pilot helicopter and for operations at remote sites or in emergency medical services

- o Convertible engine propulsion--to provide integrated flight and propulsion control modes for convertible powered rotorcraft and to evaluate advanced convertible engine concepts

- o Composite structures--to achieve effective use of advanced composites in highly loaded airframe structures

- o Advanced transmission systems--to produce more reliable, more efficient, and lighter weight transmissions for advancd turboprop, geared turbofan, and rotorcraft

- o Supersonic STOL/STOVL aircraft--to provide technology for advanced, supersonic, STOL/STOVL fighters able to operate from a variety of surfaces

- o STOVL experimental aircraft--to conduct flight tests of advanced STOVL aircraft concepts.

E. Aeronautics Beyond the Year 2000

At the end of the 20th century, a substantial potential will still exist for major advances in each of the aeronautical disciplines--aerodynamics, structures and materials, propulsion, and controls--and, perhaps of even more

significance, in abilities to combine individual advances into integrated technology for totally new aircraft systems. In addition, continued progress in related areas such as electronics, computer science, artificial intelligence, fiber optics, laser technology, and quite probably some fields not yet identifiable, will increase further the potential for progress in aeronautics over the next century.

Technologies for conventional subsonic transports, general aviation, and helicopters, all of which are major integral components of today's aviation, will continue to be important for many years into the next century. NASA will continue to develop technology for necessary improvements in the safety, productivity, and operational effectiveness of subsonic transports and in the efficiency, safety, and automation of the tasks performed by general aviation pilots. Increases in the all-weather capability and productivity of conventional helicopters and reduction of their noise and vibration will greatly expand their use in civil transportation, as well as in the special-purpose, utility, and military missions they perform today.

But probably of even more significance will be new opportunities and challenges connected with supersonic cruise, high-speed rotorcraft, short-haul subsonic transportation, and hypersonic flight.

1. Supersonic Cruise

Advances in supersonic cruise technology will provide important options for civil transportation, as well as for military aircraft. The next century will be characterized by several trends that are almost certain to alter the outlook for long-range transportation. World population will continue to grow, and the largest component of that growth--over 75 percent--will be in the developing nations. The growth of population and industry in the Pacific Basin, South America, Asia, and Africa--and the resulting increase in trade and multinational business--will create a market for over-ocean transportation with stage lengths considerably greater than those over the North Atlantic. Those long stages and the large fraction of travel that will be business oriented, rather than tourist oriented, will increase the value of reducing trip time and increasing productivity, and will precipitate renewed interest in supersonic transportation.

The Concorde already has proven the technical feasibility of supersonic air transportation, but also has proven that a system based on technology of the 1960s cannot be economically viable. Research conducted since termination of the U.S. supersonic transport program has resulted in considerable optimism that a supersonic transport can be economically viable and environmentally acceptable. Design studies conducted by the major aircraft manufacturers indicate that an advanced technology supersonic transport could carry 300 to 400 passengers over intercontinental ranges at more than three times the speed and productivity of today's subsonic transports. Operating cost estimates suggest that little if any surcharges over tourist fares would be required, and some configuration approaches appear to promise sonic boom overpressures that would be sufficiently low that flight over land would be practical.

Supersonic-cruise technology also is important for development of combat aircraft. Recent studies and combat experience indicate that sustained supersonic cruise, coupled with high maneuver capability, would provide a

considerable increase in combat effectiveness and survivability. In addition, the higher engine installed thrust-to-weight ratios associated with supersonic cruise capabilities increase the feasibility of short takeoff and vertical landing capabilities for future fighters.

2. High-Speed Rotorcraft

Although an order of magnitude slower than supersonic aircraft, new rotary-wing vehicles will be much faster than present-day helicopters and, therefore, able to assume a much broader role in both civil and military operations. Tilt-rotor technology developed jointly by NASA and the U.S. Army makes it possible for an aircraft to retain the vertical flight and hover advantages of a helicopter while being capable of efficient, smooth, quiet, forward flight at speeds approaching those of current propeller-driven airplanes. That capability is a first, but important, step toward entirely new generations of high-speed rotary wing aircraft for a variety of military applications and for civil missions including rescue, emergency medical service, and police work.

The tilt-rotor aircraft's increased speed, range, economy, payload, and comfort will provide the basis for large-scale inter-city and inter-region civil transportation. Also, its capability for combined vertical and forward flight will be important in satisfying worldwide needs created by conditions as disparate as urban congestion in highly developed areas and primitive terrain in developing areas. Problems encountered in construction activities at remote sites may focus future attention on another feature of rotary-wing technology--the heavy lift capability of very large helicopters, particularly in the higher-efficiency, reduced-weight versions that current rotorcraft research will make possible.

3. Short-Haul Transports

Although supersonic transports will provide much of future long-range air travel, a large fraction of air transportation in the United States and, even more, in Europe and elsewhere will consist of trips with stage lengths of 160 to 800 kilometers. In the next century, as population grows and shifts away from the older metropolitan areas and as new urban areas and industrial centers develop, the need for efficient, comfortable, short-haul air transportation will increase rapidly. Small commuter aircraft mostly will be replaced by aircraft that have capacities of 50 to 100 passengers or more, that are designed to large-transport standards of air worthiness, operation, safety, and dependability, and that also are designed for maximum efficiency during climb, descent, and short-stage-length flight. The new aircraft also will be able to operate safely and quietly at relatively small airports and on short runways at hub terminals.

Advanced turboprop technology now under development will be an important contributor to that future generation of commuter aircraft by providing important improvements in fuel economy. The new short-haul transports also will benefit from research now under way for long-haul transports in areas such as drag reduction, lightweight structures, active controls, and safety. They also may employ propulsive lift for takeoffs from short runways.

4. Hypersonic Flight

The X-15 research airplane allowed some exploration of the hypersonic regime in the early 1960s and, in fact, helped set the stage for the Shuttle and other space vehicles that must pass through the hypersonic regime on the way to and from orbit. Development of capabilities for sustained hypersonic flight entails technical problems in propulsion and aerodynamic heating that will be more difficult to solve. However, research has indicated that they can be solved, making hypersonic flight operations in the next century practical and perhaps even routine. Long-range cruise missiles with supersonic-combustion ramjet (scramjet) propulsion systems burning high-density hydrocarbon fuels may be the first generation of operational hypersonic vehicles, followed by strategic reconnaissance aircraft able to cruise at Mach 5 to Mach 7 at very high altitudes. There also is renewed interest in a hypersonic maneuvering airplane capable of sustained operation both in the atmosphere and in low orbit. Equipped with a combination of scramjet and rocket propulsion to match the transatmospheric envelope, it probably would be able to take off, as well as land, horizontally. Technology development involving highly coordinated systems research in the propulsion, aerodynamics, materials, structures, and controls disciplines will be required and will have to be conducted on the basis of postulated future vehicle requirements until actual military spaceflight needs can be defined.

5. Research Opportunities

The Aeronautics Research and Technology Base effort, the primary source of the seeds for long-range future growth, well may lead to additional and perhaps even more important next-century developments that now cannot be identified. Two areas of extreme importance to developments in all the types of aeronautical vehicles are the growing dependence of aircraft and engine design on numerical simulation and the use of microelectronics in aircraft controls.

An ability to compute fluid dynamics is essential for enhancing understanding of aeronautical phenomena and for facilitating the aeronautical design process. By the year 2000, solutions to the full Navier-Stokes equations should be possible, providing exact solutions for the real flow of gases, allowing accurate modeling of turbulence and separated flow, and opening the way to a broad range of control mechanisms for improving aerodynamic flows.

Technology advances that should be incorporated into aircraft of the next century will require that systems integration capabilities be developed to a degree more advanced than those reflected in the Space Shuttle, the best current example of a highly integrated aerospace vehicle. Highly reliable flight controls, electric power systems, and electromechanical actuators will allow replacement of mechanical, hydraulic, and pneumatic systems with all-electric systems having higher reliability and lower weight. Fiber optics will make possible fly-by-light systems providing still greater flexibility, weight reduction, and protection from lightning effects. Technology will be available for active controls to alleviate structural loads and suppress flutter, thereby significantly improving ride qualities and reducing pilot workloads and structural fatigue.

Many of the tools and facilities that will be required to support research and technology and vehicle development into the 21st century either already exist or are under development. NASA's impressive capability in low-speed and high-speed wind tunnels recently has been augmented with the National Transonic Facility and will be enhanced further when the 40X80X120-foot wind tunnel at Ames Research Center becomes operational. However, additional capabilities will be needed for large-scale, real-gas, hypersonic engine testing, for icing research, and for large-scale, integrated airframe-propulsion systems research in which altitude, temperature, and speed effects can be studied concurrently.

In addition to those types of ground-based facilities, technology development will continue to require flight research as an essential element. Thus, new experimental vehicles probably will be required in the areas of hypersonics, supersonic hort-takeoff and vertical landing, advanced supersonic cruise aircraft, and very high speed rotorcraft.

The future of aeronautics in the next century is replete with technology opportunities for growth and advancement even more impressive and exciting than those witnessed in the present century, but successful realization will require continued effort and commitment. NASA's research is providing, and will continue to provide, a solid foundation from which NASA will proceed effectively in directions it selects on the basis of national needs and priorities.

F. Institution

Two of the eight NASA goals listed in Section A of this chapter, the first and the last, are fundamental to institutional management. As an important step toward meeting the first, creation of a work environment that will enable the Agency to achieve and maintain a work force of highest excellence, NASA has undertaken as a priority activity recruitment of recent graduates of distinction in science and engineering. The current scientist and engineering complement of 10,900 is expected to grow to approximately 11,500 by the end of FY 1989. Of particular significance is that the buildup is occurring within a stable ceiling of about 21,000 for NASA's total permanent work force.

The last of the eight goals calls for developing and applying advanced technology and management techniques and procedures to obtain optimum productivity. Two major activities are being conducted toward meeting that goal. The first is preservation, enhancement, and construction of aeronautical and space facilities, especially facilities essential to support the growing number of Space Shuttle flights and the payloads they carry. The second, computer systems management, has the objectives of ensuring that the best computer tools are available at the right time and at the lowest cost, fostering the use of computer systems to increase management productivity, and advancing computer and computer-related technology for the benefit of NASA and the Nation.

APPENDIX 7

Report of the White House Science Council

May 1983

OFFICE OF SCIENCE AND TECHNOLOGY POLICY
EXECUTIVE OFFICE OF THE PRESIDENT
WASHINGTON, D.C. 20500

THE WHITE HOUSE

WASHINGTON

May 20, 1983

Dr. G. A. Keyworth, II
Science Advisor to the
President
Washington, D.C. 20500

Dear Jay:

The White House Science Council at its meeting today reviewed and approved the report of its Federal Laboratory Review Panel. I am pleased to transmit the report to you herewith.

As David Packard, the Panel's chairman points out, the Federal laboratories have several serious deficiencies, and a number of the laboratories do not meet the quality and productivity standards that can be expected of them.

Implementation of the Panel's recommendations would help overcome many of these deficiencies and better utilize the great potential of the laboratories. I urge you to help see that these recommendations are, in fact, acted upon expeditiously. The Council stands ready to help, as appropriate.

Sincerely,

Sol

Solomon J. Buchsbaum
Chairman
White House Science Council

May 20, 1983

Dr. Solomon J. Buchsbaum
Chairman
White House Science Council
Executive Office of the President
Office of Science and Technology Policy
Washington, D. C. 20500

Dear Sol:

I am pleased to transmit to you, with this letter, the report of the White House Science Council's Federal Laboratory Review Panel.

In summary, the Panel found that the Federal laboratories have several serious deficiencies, and consequently, a number of the laboratories do not meet the quality and productivity standards that can be expected of them. We cannot overemphasize the need to correct these deficiencies.

The Panel's most important recommendations concern the missions and management of the laboratories. First, the parent agencies of the Federal laboratories must review and redefine the missions of these laboratories. At most multiprogram laboratories, the research activities could be reduced in breadth, and reconcentrated on those areas most relevant to the missions and of demonstrated excellence. The size of a laboratory must be determined by its mission requirements and by the quality of its work.

Second, the laboratories must be held more accountable for the quality and productivity of their research and development. There should be an oversight function that is responsible for the continuing excellence of the laboratories. This function could be performed by an external oversight committee. Micromanagement, or excessive detailed direction to the laboratories, focusing on procedures rather than content, should be stopped.

Dr. Solomon J. Buchsbaum May 20, 1983

The Panel has also made recommendations to relieve the constraints on Federal laboratories with regard to personnel administration; to provide funding in a way more conducive to rational planning; and to increase the collaboration of Federal laboratories with universities and industry. This last point is certainly not the least important. At a time when the nation's economic and defense leadership is increasingly challenged, greater synergism between all our R&D institutions is a must.

Sincerely,

David Packard

DP/lgk

FINDINGS AND RECOMMENDATIONS

The Federal Laboratory Review Panel was established by the White House Science Council. Dr. George A. Keyworth asked the Panel to review the Federal laboratories and to recommend actions to improve their use and performance. The Panel has completed an extensive survey of both government-operated and contractor-operated laboratories. The Panel is convinced that the Federal laboratories have great potential and are an essential part of the American institutions where R&D is performed and scientists and engineers receive training. At the same time, the Panel has observed a number of serious deficiencies in the Federal laboratories. These deficiencies limit both the quality and the cost-effectiveness of research done by the Federal laboratories. The negative effects of these deficiencies have increased to serious levels during the past decade.

The Panel has focused on several major aspects of the Federal laboratories, including *mission*—important for defining the relationship of these laboratories to other scientific institutions and also for assuring the best performance of each laboratory; *personnel*—the key laboratory resource upon which excellence depends; *funding*—an important factor in the laboratory's stability and long range organizational integrity; *management*—crucial in creating and maintaining an environment conducive to first class research; *interaction of the Federal laboratories with universities, industry, and users of research results*—necessary for greater relevance and usefulness of the laboratories' research results.

In this summary, we present the Panel's major recommendations. We believe they demand the attention of both the Administration and Congress. At a time when the nation's economic and military competitiveness is increasingly challenged, it is imperative that the nation gets the optimum return from its investment in the Federal laboratories. The Panel believes that all the recommendations, if implemented, will improve the quality of the work done by the Federal laboratories.

1. *Mission*

The Panel believes that clearly defined missions consistent with the appropriate roles for Federal laboratories*, are important to the vitality of any laboratory. Of the laboratories visited, those with well defined missions clearly were better performers than those with poorly defined missions. Those laboratories with both well defined missions *and* close interaction with the users of their research appeared to be the most effective of all.

* The appropriate roles for Federal laboratories are discussed in the Introduction section of the report.

Recommendations

1-1. As a top management priority, Federal agencies should reexamine the missions of their laboratories. Together with the laboratory directors, the agencies should redefine the missions as necessary to ensure that they are consistent with the appropriate roles for Federal laboratories. The missions must be made sufficiently clear and specific to guide the agency and the laboratories in setting goals against which the laboratories' performance can be evaluated.

1-2. The size of each Federal laboratory should be determined by its missions and the quality of its work. That size should be allowed to increase or decrease (to zero if necessary) depending on mission requirements, but it should not fluctuate randomly. Preservation of the laboratory is *not* a mission.

2. *Personnel*

The Panel believes that almost all of the Federal laboratories, both government-operated and contractor-operated, suffer serious disadvantages in their inabilities to attract, retain, and motivate scientific and technical personnel required to fulfill their missions. The principal disadvantage is the inability of the Federal laboratories, particularly those under the Civil Service system, to provide scientists and engineers with competitive compensation at entry and top senior levels.

Recommendations

2-1. Administrative and legislative actions should be initiated now to create, at government-operated laboratories, a scientific/technical personnel system independent of current Civil Service personnel systems.

2-2. Contracts governing government-owned, contractor-operated laboratories should be rewritten to permit the contractor to establish and carry out an independent salary administration.

3. *Funding*

The Panel is concerned that the direction and performance of the Federal laboratories is less than optimal because of serious problems with the continuity of research funding. Supporting high quality research requires stability and a long-range view.

The Panel also believes that the Federal laboratory directors are not allowed enough flexibility to exploit innovative scientific opportunities. However, added flexibility will be an improvement only if accompanied by increased accountability for performance and results.

Recommendations

3-1. The Congress and the Office of Management and Budget should authorize funding for R&D programs on a predictable multiyear basis so that staffing levels and research activities at the Federal laboratories can be properly planned.

3-2. At least 5 percent and up to 10 percent of the annual funding

of the Federal laboratories should be devoted to programs of independent research and development at the laboratory directors' discretion. Federal agencies should establish a mechanism to evaluate the results of such work, with the size and continuation of discretionary funds related to laboratory performance. In order to encourage cooperative research programs, the laboratory directors should have the authority, and be encouraged, to spend part of the discretionary funds at appropriate universities and industries.

4. Management

The Panel concludes that some agencies give excessively detailed management direction to the laboratories (i.e. micromanagement). At the same time, they do not hold the laboratories sufficiently accountable for output in terms of quality and productivity.

Recommendations

4-1. For each Federal laboratory, there should be an external oversight function responsible for assuring the continuing excellence of the laboratory. This function could be performed by a committee which should include strong industry and university representation. This committee would spend enough time at the laboratory to become familiar with the laboratory's strengths and weaknesses. It would focus on productivity *and* on the excellence, relevance, and appropriateness of research. The oversight committee would make recommendations to the agency and inform the laboratory director of these recommendations. Those recommendations would be taken into account by the agency and laboratory in their budget decisions. In addition, the committee would also give special attention to reducing micromanagement by the sponsoring agency.

4-2. Federal agencies should rely to a greater extent on the competitive peer review process for funding basic research at the laboratories.

4-3. The laboratory director must be held accountable for the quality, relevance, and productivity of the laboratory. Appointment of the director should be for a finite term, with the option of extending or abbreviating the term depending on the performance of the director and the laboratory.

5. Interaction with Universities, Industry, and Users of Research Results

The Panel feels that the degree of interaction of Federal laboratories with universities and industry varies among laboratories, but has not been strong traditionally. The national interest demands that this collaboration be stronger to ensure continued advances in scientific knowledge and its translation into useful technology.

Recommendations

5-1. Federal laboratories should encourage much more access to their facilities by universities and industry.

5-2. R&D interactions between Federal laboratories and industry should be greatly increased by more exchange of knowledge and personnel, collaborative projects, and industry funding of laboratory work, provided an oversight mechanism is established to prevent unfair competitive practices.

5-3. Contracting by agencies and laboratories for universities and industry to conduct R&D should be encouraged by simplifying the necessary Federal procurement procedures. The procurement process should give laboratory directors greater flexibility in contracting.

6. Conclusion

In addition to the major recommendations contained in this summary, there are several others in the body of the report. We believe that the Panel's recommendations, when implemented, will make constructive changes to revitalize the Federal laboratories so that their wealth of talent and facilities will contribute more effectively to our citizens' health, our nation's defense, and our economic growth.

INTRODUCTION

Background

The White House Science Council's Federal Laboratory Review Panel[1] was appointed by Dr. Solomon J. Buchsbaum, Chairman of the Council, in March 1982. Dr. George A. Keyworth, Science Advisor to the President, asked the Panel to review the Federal laboratories and to recommend actions to improve their use and performance. The Panel was specifically charged to look at laboratory missions, identify any systemic impediments to performance, and determine whether this nation is getting the optimum return on its substantial investment in talent and facilities at the Federal laboratories.

There are more than 700 Federal laboratories, set up at various times for specific purposes. Over time, their activities have tended to expand and diversify, partly because they succeeded in their original tasks and partly because mission requirements changed. In some cases, this expansion has resulted in a dilution and weakening of purpose, mission, and capability.

Panel Activities

Of the Federal agencies with research and development (R&D) laboratories, the Panel concentrated on six with the major share of laboratory funding: The Departments of Defense, Agriculture, Commerce, Energy, and Health and Human Services, and the National Aeronautics and Space Administration. Panel members visited several large multiprogram R&D laboratories[2] and met with top agency representatives responsible for laboratory management. The Panel also examined past studies of Federal laboratories[3], and was kept informed of ongoing reviews by the President's Private Sector Survey and the Energy Research Advisory Board. The Panel invited input from industry and universities and took those into account in its deliberations[4].

Overall Findings

The Panel did not review the Federal laboratories in sufficient detail to evaluate fully the quality of the work being done or to measure the Federal laboratories' contributions in relation to university and industrial research. The Panel did find highly competent people, important research programs, and unique large facilities that would be beyond the means of both universities and industry. The Panel also identified a number of serious deficiencies at the Federal laboratories that limit both the quality and cost effectiveness of the work done there. These deficiencies are not new, but their negative effects have increased to serious levels over the past decade. The nation's return on its investment in support of the laboratories is being undercut seriously by vagueness and inconsistencies in some of the laboratories' missions,

[1] See Appendix A for a list of Panel members.
[2] See Appendix B for list of laboratories visited
[3] See Appendix C for list of major past studies
[4] See Appendix D for individuals, corporations and organizations

and by the increasingly pervasive effects of impediments described later in this report.

R&D Roles

The Panel believes that Federal laboratories play important roles in the nation's scientific and engineering enterprise—roles that complement those played by industry and universities. Specifically, the Panel believes that these roles are appropriate for the Federal laboratories:

- Perform basic and applied research in areas where the Federal government has a legitimate responsibility, including nuclear energy, agriculture, health sciences, and development of military technology and equipment.
- Conduct other research projects of a long range nature that require unique, capital-intensive facilities and multidisciplinary approaches.
- Build and manage large multiuser technical facilities, and encourage universities and industry to use them.
- Contribute, through cooperative programs with universities, to the education of scientists and engineers in applied research where university capabilities may be limited.
- Perform research and provide services on important national standards, metrology, environmental protection, health and safety.
- Provide special services, such as producing radioactive material, maintaining banks or libraries of materials (such as agricultural plant material), and provide calibration services such as those relating to time, and other physical measurements.
- Develop commercial products only when that work has industry cooperation *and* is directly related to the laboratory's unique capabilities.

These roles are intermediate between those of universities and industry. Both Federal laboratories and universities are very important to support a high rate of technological advance in the U.S. Universities often excel in basic research, and they provide the additional important benefit of producing future scientific talent. On the other hand, Federal laboratories and commercial firms have many common capabilities and interests. Commercial firms are, by far, the most effective in applying research results to broader, practical uses, and to deliver products and services to the market. They also have the best capability to conduct activities to improve industrial competitiveness and productivity. The national investment in R&D must be justified by the contributions of the R&D institutions to the nation's goals of health, strong economic growth and national defense. These contributions can be optimum only if these institutions fulfill their proper roles and complement one another, so that their research contributes to U.S. leadership in technologies and products. The balance in Federal funding between Federal laboratories, universities, and commercial firms may not be optimum and needs further attention.

Nature of Recommendations

The recommendations in this report are made in the framework of the roles described above. They aim to bring the Federal laboratories to the necessary level of excellence and productivity to justify a continuing high level of investment in them. The Panel believes strongly that action on these recommendations, some of which have been made before, is well overdue. The Administration and the Congress can and should make major corrections in 1983 to improve the quality and productivity of the Federal laboratories.

The recommendations address the following factors, which are vital to the laboratories' ability to perform and to contribute to the nation's well-being and national security:

- Clear *missions* that allow firm goals to be set against which the performance of the laboratories can be measured.
- Appropriate *resources*, most importantly adequate scientific talent, for carrying out the missions.
- A *management* of the laboratories that fosters an environment conducive to first-class research.
- Strong *interaction with universities, industry, and users of research results*, to maximize the complementary use of talent and resources; to assure application of results to broader, practical uses; and to minimize undue overlap and unfair competition.

1. MISSION

The Panel believes that clearly defined missions are important to the vitality of any laboratory. Of the laboratories visited, those that had well defined missions clearly were better performers than those that did not. Those laboratories which had both well defined missions *and* close interaction with the users of their research seemed the most effective.

The Panel observed that some of the laboratories did have a clearly defined mission for a part—often a major part—of their work, but the balance of the work was often fragmented and unrelated to their main activity. This phenomenon frequently occurs when a national need that justified the original mission of a laboratory becomes of lower priority. The laboratory then tends to diversify into other work to occupy its staff and preserve institutional stability. The DOE laboratories offer an example of this tendency. During the mid-1970s, work related to their original missions under the Atomic Energy Commission decreased. Research on alternate energy resources was used to fill the gap and increase the activity level at several of the large DOE laboratories. The new missions were not very clearly defined or carefully considered at any level of management.

Given the great concern at that time about future energy sources, a lot of money was made available to the laboratories. But, very little came of this effort, and in the 1980s most of the research on alternate energy resources has been cut back, transferred to industry, or transformed into longer-term exploratory development. These changes have left several of the DOE laboratories without well defined missions. The absence of missions, in turn, contributes to less than optimum use and performance.

The Panel believes that the clearer a laboratory's missions are, the better its performance will be. It would be better to reduce the size of a laboratory to meet the real needs of its legitimate missions than to maintain its size by filling in with unrelated research projects.

A laboratory whose original missions no longer serve high-priority national needs may be able to acquire new missions. To be carried out competently, these missions must be consistent with the laboratory's existing strengths and expertise. If necessary, a laboratory without a mission should be shut down.

The Panel also concludes that some of the work done by the Federal laboratories could have been done as well, or possibly better, by private industry or by universities (e.g., engine designs, batteries and fuel cells, electric power transmission and distribution, design of specific airframe/engine installation concepts, and renewable energy sources). This would have been less likely to happen if the missions of the Federal laboratories had been defined to encourage cooperation rather than competition with industry and universities. Most research projects at Federal laboratories could benefit from related research in universities

and in industry and could be guided by prospective users, either in industry or in government agencies.

Finally, the Panel observed a certain amount of overlap and competition between some laboratories, but this should not be a problem if the main missions are clearly defined. Some competition is good. For example, the competition between Lawrence Livermore and Los Alamos in nuclear weapons development seemed to be an important factor in the high quality of weapons work in both laboratories.

The breadth of research activities at most Federal laboratories could be reduced and the depth increased in those areas of demonstrated excellence and mission relevance. The laboratories could also take better advantage of modern communications technology for information exchange among a large number of people over wide geographic areas.

Recommendations

1-1. As a top management priority, Federal agencies should reexamine the missions of their laboratories. Together with the laboratory directors, the agencies should redefine the missions as necessary to ensure that they are consistent with the appropriate roles for Federal laboratories. The missions must be made sufficiently clear and specific to guide the agency and the laboratories in setting goals against which the laboratories' performance can be evaluated.

1-2. The size of each Federal laboratory should be determined by its missions and the quality of its work. That size should be allowed to increase or decrease (to zero, if necessary) depending on mission requirements, but it should not fluctuate randomly. Preservation of the laboratory is *not* a mission.

2. RESOURCES: PERSONNEL

The key to a laboratory's success is a high quality and properly motivated scientific staff. The inability of many Federal laboratories—especially those under Civil Service constraints—to attract, retain, and motivate qualified scientists and engineers is alarming. The personnel problem is most serious at government-owned, government-operated laboratories (called GOGO's) but it also affects government-owned, contractor-operated laboratories (GOCO's). At present, this situation limits the productivity of the laboratories. If not corrected, it will seriously threaten their vitality.

While middle level salaries may be competitive, the GOGO's have difficulty attracting young scientists and engineers at the entry level (GS-5 and 7) on one hand, and very experienced and qualified top-level personnel on the other. There are many reasons for this difficulty, but the main one is noncompetitive pay and benefits compared with industry and universities[1]. Furthermore, cumbersome procedures for hiring new staff make it hard to bring in new talent even when other obstacles have been overcome.

The rigidity of the Civil Service promotion and salary system limits rewards for outstanding scientists and engineers. Many of them leave the GOGO laboratories when they reach the levels where they cannot advance unless they are willing to assume management and administrative responsibilities (usually GS-12 and 13 levels). Promotion is linked to management responsibilities, and current rules do not allow for adequate recognition of scientific performance alone. Recent personnel ceilings imposed strictly on a numerical basis without distinguishing among types of staff have adversely affected the laboratories' R&D activities.

The GOCO's are not legally under the Civil Service system, but some agencies have chosen to impose ceilings on allowable reimbursements for scientific personnel.

This personnel situation leaves the Federal laboratories vulnerable to weak scientific leadership if senior qualified personnel cannot be replaced, and to declining quality of research because of inadequate infusion of young talent.

It is important that Federal laws and regulations be modified to exempt scientific and engineering personnel at Federal laboratories from the unduly rigid hiring, salary, and promotion rules of the Civil Service system. In place of these rules there should be: 1) a more flexible system that facilitates hiring, and enhances career progress for

[1] The pay discrepancy varies among laboratories. The National Institutes of Health has the largest difference between the Federal pay ceiling and the private-sector earning power of specialized academic physicians.

technically qualified personnel, and 2) an effective performance-based reward system.

The recent experiment by the Department of Defense at the Naval Weapons Center (China Lake, California) and the Naval Ocean Systems Center (San Diego, California) is considered highly successful by the participants[9]. The experiment applies a revised personnel management system which simplifies classification and bases pay, appraisal, and retention on performance. It also reduces the paperwork required to hire and promote. The experiment shows that it is possible to introduce flexibility in personnel management at the government-operated Federal laboratories.

GOCO personnel problems can be corrected by a very simple and logical step. Every contract to manage a government laboratory—whether the contractor is an industrial firm, a university, or a nonprofit organization—should give the contractor complete authority to set and carry out personnel policies that will enable the laboratory to attract retain, and motivate its professional staff. The laboratory management must have authority to set and carry out personnel policies that are comparable with those of competitors. This can be done best by the laboratory management, not by the agency.

Recommendations

2-1. Administrative and legislative actions should be initiated now to create, at government-operated laboratories, a scientific/technical personnel system that is independent of current Civil Service personnel systems. The experimental system for managing scientific and technical personnel at the Naval Weapons Center and Naval Ocean Systems Center is an example of how this can be approached.

2-2. Contracts governing government-owned, contractor-operated laboratories should be rewritten to permit the contractor to establish and carry out an independent salary administration.

2-3. Personnel ceilings at government-operated laboratories should not be used in addition to budgetary control. Federal agencies should provide budget constraints and give the laboratory directors freedom to decide how to meet them. Laboratory directors should also be allowed to make the final decisions on contracting for support services at their laboratories.

[9] See Appendix E for description of experiment.

3. RESOURCES: FUNDING

The current processes by which laboratories are funded impede rational planning and effective conduct of R&D activities. The budget process consumes too much time at too many levels, both in the agency and the laboratories. Delayed appropriation actions by Congress, often compounded by agency indecision, have dragged uncertainties in laboratory funding well into the fiscal year in which funds are to be spent. It is also clear that most laboratory directors need more flexibility to allocate funds at their laboratories. However, added flexibility will be an improvement only if accompanied by increased accountability for performance and results.

If U.S. taxpayers are to get the most return from their support of R&D, government laboratories must have sufficient discretionary funding for independent research and development. Almost every laboratory has found that the most important innovation often comes from the scientists' independent ideas of actions. Thus, the productivity of the U.S. R&D establishment depends on a vigorous independent R&D program. Yet, funding for independent R&D has been decreasing over the years.

Recommendations

3-1. The Congress and Office of Management and Budget should authorize funding for R&D programs on a predictable multiyear basis so that staffing levels and research activities at Federal laboratories can be properly planned.

3-2. At least 5 percent, and up to 10 percent, of the annual funding of the Federal laboratories should be devoted to programs of independent research and development at the laboratory directors' discretion. Federal agencies should establish a mechanism to evaluate the results of such work, with the size and continuation of discretionary funds related to laboratory performance. In order to encourage cooperative research programs, the laboratory directors should have the authority, and be encouraged, to spend part of the discretionary funds at appropriate universities and industries.

3-3. Federal laboratories should be allowed to carry forward remaining funds into the next fiscal year. This would eliminate the wasteful practice of hurried spending at the end of each fiscal year.

4. MANAGEMENT

It is clear to the Panel that excessively detailed direction of laboratory R&D activities from agency headquarters, known as micromanagement, has seriously impaired R&D performance in some laboratories. Numerous detailed external directions are given as to how work should be done, while at the same time, the overall missions and goals of the laboratories are inadequately defined. This trend must be reversed.

The micromanagement problem is most serious at the Department of Energy (DOE) laboratories and has its roots in the lack of stability in the DOE itself. The Department has changed leadership many times, and its mission has changed and diversified too often, to the point where it is no longer clear. The Department also must respond to a much larger number of Congressional committees and subcommittees than other Federal agencies do.

Perhaps the most serious deficiency of the Federal laboratories is their lack of accountability. They are not subject to the competitive driving force of the peer review system as the universities are. Nor has their survival depended on satisfying the cost effectiveness and relevance constraints of industrial R&D laboratories. In the absence of economic and competitive forces, the Federal laboratories must be held accountable by their agencies. Unfortunately, in most cases, the agencies' oversight means an excessive amount of reporting and paperwork, but inadequate scrutiny of the quality and relevance of the laboratories' activities.

The current review mechanism often focuses on evaluation of proposed work rather than actual performance. Review processes also emphasize the more easily measurable criteria (e.g. time and cost) rather than the more difficult but important criteria of excellence, relevance to national needs, and appropriateness[1]. Review committees usually have only advisory authority and report to the laboratory directors.

As a result of this kind of oversight, there are many opportunities for low-quality research in pedestrian subjects or in areas inappropriate for government involvement. R&D in Federal laboratories, even within the same agency, is often poorly coordinated, leading to unproductive overlap among laboratories and missed opportunities for synergism.

A proper balance of basic research activities between the laboratories and the universities is important to maintain both the nation's scientific base and educational capability. A good way to assure a proper balance

---

[1] Excellence: Is this research of high quality? Is this researcher competent?

Relevance: Does this research address an important scientific question to solve a national need? Is it related to the agency's mission?

Appropriateness: Is this laboratory the best place to perform this research? Should the Federal government be funding this research?

is to insist upon excellence as a criterion for support. The competitive peer review process, though imperfect, is a good mechanism for evaluating basic research. Yet, among the agencies with major laboratories, only the National Institutes of Health rely on this process systematically and, even then, only for extramural programs.

Different agencies have different forms of laboratory management. Even within the Department of Energy, operating procedures differ: some laboratories are operated by universities, others by private companies, still others by government employees. Each form of management presents advantages and disadvantages, but the quality of management is crucial to a laboratory's performance. Federal agencies must insist on highly competent laboratory directors. The agencies must then make sure that the laboratory directors understand their missions and the place of their laboratories in the overall work of the agency. Each agency should involve the laboratory directors in developing an overall R&D plan. This would encourage teamwork and increase synergism between the laboratories.

Recommendations

4-1. For each Federal laboratory, there should be an oversight function responsible for assuring the continuing excellence of the laboratory. This function could be performed by an external committee which should include strong industry and university representation. This committee would spend enough time at the laboratory to become familiar with the laboratory's strengths and weaknesses. It would focus on productivity *and* on the excellence, relevance, and appropriateness of research. The oversight committee would make recommendations to the agency and inform the laboratory director of these recommendations. Those recommendations would be taken into account by the agency and laboratory in their budget decisions. In addition, the committee would give special attention to reducing micromanagement by the sponsoring agency.

4-2. Federal agencies should rely to a greater extent on the competitive peer review process for funding basic research at their laboratories.

4-3. The laboratory director must be held accountable for the quality, relevance, and productivity of the laboratory. Appointment of the director should be for a finite term, with the option of extending or abbreviating the term depending on the performance of the director and the laboratory.

4-4. The above recommendations apply to all Federal agencies. The management of the Department of Energy presents an additional special problem, and the Panel recommends that the Administration and Congress work together to stabilize and strengthen DOE management and to define and affirm its mission. Congress should also refocus its oversight of DOE R&D into a significantly smaller number of committees.

5. INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

The United States can no longer afford the luxury of isolating its government laboratories from university and industry laboratories. Although endowed with the best research institutions in the world, this country is increasingly challenged in its military and economic competitiveness. The national interest demands that the Federal laboratories collaborate with universities and industry to ensure continued advances in scientific knowledge and its translation into useful technology. The Federal laboratories must be more responsive to national needs.

The ultimate purpose of Federal support for R&D is to develop the science and technology base needed for a strong national defense, for the health and well-being of U.S. citizens, and for a healthy U.S. economy. Federal laboratories should recognize that they are an important part of the partnership with universities and industry in meeting this goal. A strong cooperative relationship must exist between Federal laboratories, universities, industry and other users of the laboratories' research results.

Federal laboratories have felt traditionally that they are part of the government, committed to its highest service and totally dependent on it for support. They perceived industry as an awkward partner with a different value system. Although the degree of interaction with universities and industry varied among the laboratories visited, the Panel feels that this interaction could be increased at all Federal laboratories.

One means of interaction is through R&D contracts. The current Federal procurement system discourages agencies and GOGO laboratories from contracting with universities and industry. Procedural requirements for doing so are far more cumbersome than for assigning work to the Federal laboratories. As a result, many parent agencies have assigned to the laboratories work that would be more appropriately performed elsewhere, and the GOGO laboratories have been reluctant to contract with universities and industry. The Panel believes that this situation has caused the balance of R&D funding in many agencies to shift in favor of the Federal laboratories at the expense of the universities and industry for over a decade. This problem is most severe with the DOE and DOD, and least with the NIH.

A final note on interaction between Federal laboratories and users of research results concerns the DOD. Since the major task of DOD laboratories is to enhance the capability of our military forces, greater communication between the DOD's operating forces and its laboratories would benefit both parties. This communication is currently hampered by the many layers of management between the laboratories and the operating forces.

Recommendations

5-1. Federal laboratories should encourage much more access to their facilities by universities and industry.

5-2. R&D interactions between Federal laboratories and industry should be greatly increased by more exchange of knowledge and personnel, collaborative projects, and industry funding of laboratory work, provided an oversight mechanism is established to prevent unfair competitive practices.

5-3. Contracting by agencies and laboratories for universities and industry to conduct R&D should be encouraged by simplifying the necessary Federal procurement procedures. The procurement process should give laboratory directors greater flexibility in contracting.

5-4. Support to the military operating forces should be an important criterion among others for measuring performance of the DOD laboratories.

ACKNOWLEDGE-MENTS

The Panel wishes to thank the directors and staff of the laboratories that we visited for their cooperation and assistance in the conduct of this review. The Panel also expresses appreciation to all the representatives from industry, universities, and government who formally and informally provided valuable input to the Panel.

APPENDIX E

NOSC/NWC PERSONNEL DEMONSTRATION PROJECT

Area of Interest:

Demonstration Project
(An Experiment in Federal Personnel Management)

Background Statement

Under Title VI of the Civil Service Reform Act (CSRA) of 1978, there were provisions for federal agencies to obtain approval from the Office of Personnel Management to conduct a demonstration project to determine if the removal of personnel management constraints and changes to personnel regulations could increase effectiveness and efficiency in the work force. By law, such experiments were limited to a total of 10 active projects, could last for a maximum of five years, and were limited to a maximum of 5,000 employees.

To date only one project has been approved, and that is the Navy's joint Naval Ocean Systems Center/Naval Weapons Center Demonstration Project, initiated in July 1980. The Project allows waiver of certain personnel-related laws and regulations; however, it does not waive leave, insurance, annuity, Hatch Act, or EEO rules or regulations. Basically, it is a revised personnel management system providing simplified position classification, performance linked pay and appraisal, and performance based retention.

The following Executive Summary provides basic information on this Center's personnel Demonstration Project. Its purpose, description, and operating policies are covered. If you would like more detailed background on the Project, a suggested contact is:

Contact:

Bob Glen
Demonstration Project Manager (Code 0902)
Extension 3196

Executive Summary

Personnel management under the Civil Service system has experienced a number of problems; key examples are:

(1) Classification—complex and outdated position standards which delay recruitment and promotions, limit organizational flexibility to administer personnel resources, and place personnel staffs in an adversarial role with line management mission, product, and service obligations.

(2) Performance appraisal—unsatisfactory pay incentives to reward good and penalize poor performance, and the inability, through performance planning and mutual employee-supervisor goal setting, to objectively establish and measure employee effectiveness in relation to organizational goals.

(3) Merit pay—lack of sufficient incentives and flexibility in dealing with all levels of the work force and in offering recent college graduates and other potential employees pay which will keep pace with professional growth, performance and responsibilities demonstrated.

(4) Reduction-in-force—inability to recognize performance as a major criterion in RIF situations and to avoid adverse effects upon good performers who happen to have low retention standing or who may be recently-hired female or minority employees.

The NOSC/NWC Demonstration Project was established to address the above problem areas within the existing personnel system and to show that the effectiveness of federal organizations can be enhanced by allowing greater line management control over personnel functions.

Purpose

The intent of this Project is to permit increased line management involvement in major personnel-related decisions, such as recruitment, compensation, training, appraisal, and rewards. The line manager is the primary decision maker on personnel issues of pay, classification, merit, and job assignments which have important effects upon motivation, performance, and organizational effectiveness. To accomplish these changes, the Demo Project includes (1) a more flexible, manageable, and understandable classification system which aggregates several GS grade levels into broad pay bands; (2) a performance appraisal system that links performance goals, compensation, and organizational effectiveness; (3) an expanded application of the CSRA merit pay concept for both supervisory and non-supervisory employees; and (4) an emphasis on performance as a primary criterion in the retention process while retaining tenure, veterans preference, and length-of-service factors.

Types and Number of Participating Employees

In keeping with the 5,000 employee limit in the Project, the two Centers have included the following full-time personnel in the Demo Project:

	NOSC	NWC
Scientists and Engineers, and Senior Professional Staff	1,284	1,444
Technicians	332	586
Administrative Specialists	223	395
Technical Specialists	171	183
Clerical	360	–
	2,370	2,610
	4,980	

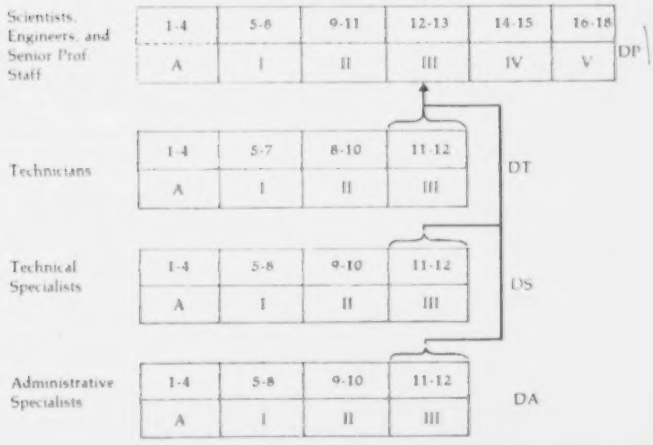
Scientists and engineers and all GS-13-15 personnel entered the Project when it began in July 1980. The GS-12 Administrative and Technical Specialists entered the Project in January 1981 with the Technicians following in August 1981 and the GS-11 and below Administrative and Technical Specialists being included in August 1982.

Since both Centers' clerical population could not be added to the Project without exceeding the 5,000 person limitation, it was decided to include only NOSC's clerical personnel in August 1982, in order to ensure an opportunity for full evaluation of the Project's concepts for all of the above career paths.

Basic Features

Implementation procedures for the Project vary somewhat between the two Centers in relation to unique management needs and styles. However, both Centers have a similar basic approach to pay, performance appraisal, and position classification. Under the experimental effort, both Centers have grouped 16 pay and classification grades (GS-1 through GS-16) into broad levels as noted below for the applicable career path:

Career Path Identification by Classification Level as Related to Current Grade Levels



The separate career paths incorporate at least two grades within each path. Performance appraisal serves as the basis for determining incentive pay adjustments in terms of classification standards and performance objectives established. Each career path is a competitive area for reduction-in-force purposes, and retention is determined primarily on the basis of performance appraisal.

Classification and Pay System

Each class of positions covered by the Demo Project (scientist and engineer, technician, technical specialist, and administrative specialist) reflects career progression of those having similar qualification requirements and lines of work. Pay bands in each career path reflect

entry, trainee, and journeyman levels of work for that occupational group. Series levels are included in the DP career path.

The classification system recognizes both the rank-in-person concept reflecting unique aspects of matrix and line management plus sponsor relationships as well as the rank-in-position distinctions through classification in broad classification levels. The first line supervisor is involved with classifying positions by using simplified standards for each pay level. Typical duties, responsibilities and levels of difficulty of work at each classification level are listed in a "menu" format. Supervisors then select from the appropriate classification standard for a given level. To acknowledge personal contributions and capabilities of individual employees as well as duties and responsibilities of positions, the traditional position description or PD has been retitled "Personal Activities and Capabilities" or PAC. The classification standards are computerized to allow for automatic listing of menu items, and the resulting PAC is identified by special code and stored for record purposes. PACs are quickly prepared and approached with maximum line supervision involvement and provide clear distinctions between functions, specialties and classification levels.

Scientific and engineering salaries are established consistent with labor market conditions and the applicant's experience and education. However, since the basis for the Project pay system is the General Schedule, scientists' and engineers' pay rates for the various levels of responsibility are directly keyed to the special salary rates for scientists and engineers.

Performance Linked Pay

Employees can be paid no less than the minimum pay rate established for the pay band to which assigned. The broad band has been divided into increments between the highest and lowest salary of the level (i.e., GS-12/1—13/10 for DP level III and 24 increments, each equaling approximately 1.5% of the highest salary level). Increases in pay are based on performance within available resources, and the Center's annual merit payout has been approximately 2.4% of Demo Project payroll. This figure has been derived from monies that formerly would have been paid to deserving employees in the form of QSIs, SSPs, and within-level promotions.

Employee performance is evaluated on the basis of five incentive pay groupings from performance that is demonstrably exceptional to that which is substantially below fully successful. The following identifies performance rating definitions and payout choices in terms of whether or not comparability pay (federally determined) and increments are awarded for the various levels of performance indicated.

Performance Ratings/Payout

Rating	*Definition*	*Pay*
1	Performance that is demonstrably exceptional—clearly deserving of recognition equivalent to a within-level promotion.	c + 4i or c + 3i
2	Quality performance that exceeds the fully successful standards.	c + 2i
3	Fully successful performance—meets the expected results of the performance plan. Growth and progression normal for NWC.	c + i or c
4	Below fully successful. Corrective action needed.	c/2
5	Substantially below fully successful. Serious performance deficiencies. Needs significant improvement for work to meet established standards.	0

Employees who exceed performance expectations receive incentive pay increases substantially exceeding government-wide comparability increases. Employees who fully meet performance expectations receive at least comparability, while those who do not fully meet performance expectations receive either one-half or none of the comparability increase.

Employees' salaries advance to the upper limit of a pay bank only through performance, not time-in-level. A lump sum bonus payout, corresponding to the payout shown above, is given to those employees whose salaries are at the top of the level or the pay cap. If, on the other hand, an employee receives no or limited pay increases due to marginal performance, and the minimum salary of the current pay band exceeds the present salary, the employee "migrates downward" to the next lower level. This occurs without specific adverse or performance-based action. In this manner, higher performing employees are rewarded in consonance with their contributions and poorer but minimally adequate performers have their salaries held constant. Employees whose performance is unacceptable may be removed or changed to a lower level as a performance-based or adverse action.

Reduction-in-Force

The Demonstration Project's major change in RIF procedures is the ranking of employees within each competitive level, based primarily on performance rating groupings and secondarily on the elements of tenure, veteran's preference, and length of service. The intent is to increase the probability of retaining the highest performing employees in their positions and displacing the lowest performers. "Bumping" is limited to the career path to which the employee is currently assigned. Thus, if engineering positions are abolished, clerical, technician, specialist and administrative personnel would not be bumped.

Employees can retreat to the career paths through which they progressed. Retention standing within a competitive level is determined by performance rating groups, and the high retention group(s) is placed at the top of the register in standard tenure, veteran's preference, and length of service order. Employees in lower retention groups are

placed at the bottom of the retention register, using the same standard order and are the first to be released from the competitive level. Individuals in higher retention groups always displace those in the lower group(s).

Implementation

A task team approach has been used to develop implementation ideas and create "ownership" of these important changes to the federal personnel system. This has involved representatives of career paths and various skills at the Center who are affected by the Project. Task teams involving pay, classification, performance evaluation, and communication are examples of representative groups from both managers and employees affected by the Project. They have made significant contributions to Center policies affecting all implementation aspects of the Demo-Project. Special employee groups to review provisions affecting career paths, such as technicians, have been used, also. These groups have influenced changes which have been made to pay bands, performance appraisal, and the new position classification approach. Task team policies have been developed in conjunction with NOSC task team counterparts.

As career paths have entered the Project, training has occurred in some depth on the basic features of the new system, how it works, and the responsibilities and expectations of supervisors and employees. Training sessions on performance planning and assessment, compensation, classification, and general system operation have been conducted by employees who have been trained by Personnel Department representatives. Specific topics other than those above included goal setting, motivation, communication, handling conflict, and performance monitoring. Essential to the understanding and acceptance of the Project have been efforts on communication and descriptions of the departmental Performance Review Boards (PRBs) where final performance evaluation decisions for employees are made.

Evaluation

To assess the Project results and evaluate the feasibility of applications to other federal organizations, evaluation efforts by OPM contract and internal evaluation groups at both Centers are underway. Coopers and Lybrand were awarded the OPM contract ($100 K with each Center paying one-fourth of the cost) and will provide their first report in September 1982. This Center's internal evaluation effort is headed by Dr. Ed Alden (Code 08203). The external evaluation effort will monitor the implementation of the Project and assess anticipated and unanticipated effects. The firm fixed price contract is for one year with four renewable options of one year for the five year evaluation period. To help isolate effects of the Project, changes at the two participating Centers will be compared with data from two other Navy labs, NADC and NSWC.

Factors as recruitment success, turnover, and Personnel Department performance will be evaluated, along with management issues of equity, motivation, satisfaction, mobility, line management flexibility/

accountability, and changes in the number of adverse actions. Attitude surveys are being conducted by both the internal and external evaluators, plus management audits, exit interviews, and other analyses involving recruitment, mobility, and sponsor satisfaction. OPM's major objectives for measuring the success of the Project include recruitment success, increased high performer retention, improved personnel function performance, and expanded performance-based pay systemization.

Benefits of Project

The Project is expected to demonstrate that a genuinely management-centered personnel administration process will lead to more efficient and effective use of the resources of the participating laboratories. In addition, by providing a means of real-world testing for models of improved and simplified classification and performance evaluation systems, the project will have results that can be applied throughout the federal service. Some examples of anticipated effects caused by the proposed changes and corresponding measures for evaluating these effects are depicted in Table 1.

Table 1.

Some Examples of Anticipated Effects Caused by the Proposed Changes, With Measures for Evaluating These Effects.

Change	*Anticipated effects*	*Evaluation measures*
Classification and pay	Increased recruitment success	Cost per recruit, recruit quality and quantity
	EEO commitment	Cost, quantity and quality of recruits
	Flexibility of workload assignment	Time, cost of reassignments and transfers
	Increased personnel effectiveness	Cost, management and employee satisfaction
Performance appraisal	Correlation of pay and performance	Perceived equity
	Improved EEO relations	Increased retention of high performance minorities and women
	Increased employee commitment	Satisfaction and commitment instruments
	Decreased turnover of "desirable" employees	Turnover rate of critical employees
	Increased turnover of low performers	Turnover rate
	Increased organizational effectiveness and efficiency	Peer, sponsor, and user evaluations, cost to conduct business
Retention	Retention of high performers	Retention rates
	Increased EEO effectiveness	Retention rates of minorities and women
Adverse action	Increased adverse action effectiveness	Cost, rate of successful actions

INTRODUCTION

Background

The White House Science Council's Federal Laboratory Review Panel was appointed by Dr. Solomon J. Buchsbaum, Chairman of the Council, in March 1982. The Panel was chaired by Mr. David Packard. Dr. George A. Keyworth, Science Advisor to the President, asked the Panel to review the Federal laboratories and to recommend actions to improve their use and performance. The Panel was specifically charged to look at laboratory missions, identify any systemic impediments to performance, and determine whether this Nation is getting the optimum return on its substantial investment in talent and facilities at the Federal laboratories.

There are more than 700 Federal laboratories, set up at various times for specific purposes. Over time, their activities have tended to expand and diversify, partly because they succeeded in their original tasks and partly because mission requirements changed. In some cases, this expansion has resulted in a dilution and weakening of purpose, mission, and capability.

Today these laboratories account for almost one-third of the Federal Government's annual expenditure for R&D and one-sixth of the total national R&D expenditure. Collectively, they employ almost half a million scientists and engineers. Thus, the Federal laboratories represent a significant fraction of the Nation's total science and technology enterprise.

The Federal Laboratory Review Panel issued its report (generally referred to as the Packard Report) in May 1983.[1] The Panel was convinced that the Federal laboratories have great potential and are an essential part of the American institutions where R&D is performed and where scientists and engineers receive training. At the same time the Panel stated that it had observed a number of serious deficiences that limited both the quality and cost-effectiveness of R&D done by those laboratories.

The Panel made a number of recommendations focused on mission, personnel, funding, management, and interaction of Federal laboratories with universities, industry, and users of research results. In presenting its recommendations the Panel stated: "At a time when the Nation's economic and military competitiveness is increasingly challenged, it is imperative that the Nation gets the optimum return from its investment in the Federal laboratories."

Highlights of the report were briefed to the President in July 1983. In August 1983 the President directed that the Office of Science and Technology Policy and the Office of Management and Budget lead an interagency effort to respond to the central thrust of the report's recommendations.[2]

[2] See Appendix A for Presidential memorandum.

Committee on Federal Laboratories

In response to the President's August 1983 memorandum, the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET) established a Committee on Federal Laboratories[3] to monitor implementation of the White House Science Council's recommendations. The Committee first met in October 1983 and established four working groups to monitor progress and coordinate joint action where necessary. These working groups were organized by topical areas covered in the Science Council's report, as follows:

- Mission and Management
- Personnel
- Funding
- External Interactions

The chairmen of these working groups and the chairman of the Committee worked closely to eliminate gaps and overlaps.

Although the charter of the Committee on Federal Laboratories expires on July 1, 1984, when the progress report is due to the President, it was the consensus of the Committee that the charter should be extended to allow continuation of periodic meetings to discuss mutual problems. There is also a need to continue the momentum established in responding to the Science Council's report.

Responses to the Recommendations

The President's interest in the health of Federal laboratories has caused the Packard Report to receive top management attention in the Federal agencies. In general, the agencies have been very responsive in implementing the White House Science Council's recommendations, especially when the agency head has been directly involved. Perhaps the most pervasive impact of the Science Council's report has been a heightened awareness on the part of top management in Federal agencies of the need to focus on laboratories, in terms of both their output and their institutional needs. The appropriate management attention has brought about, and will continue to bring about, a variety of improvements.

The recommendations addressed all Federal laboratories and necessarily had to deal for the most part with norms rather than specific institutions or agencies. Consequently, the responses varied from agency to agency, depending on a variety of factors. In no case did an agency disagree with the merit of the management principles or the spirit of the recommendations. The differences in degree of implementation reflect that: (1) some agencies had internal parallel studies under way and began early to effect management improvements once the Packard Report was published; (2) others had completed major related actions a few months prior to the report; and (3) some view their existing processes as already highly consistent with many of the recommendations.

---

[3]See Appendix B for a list of Committee members.

The most difficult recommendations to implement are those involving the legislative process: creating a separate scientific/technical personnel system and instituting multiyear funding for R&D. Since they affect almost all Federal agencies involved in R&D, they are being handled jointly on a government-wide basis.

In the chapters that follow, the recommendations are discussed in the same order and groupings as they appear in the White House Science Council's report. Progress on each recommendation is summarized and, where applicable, selected agency accomplishments are presented as examples. Finally, a discussion of future directions summarizes recommendations for follow-on efforts.

1. MISSION

DEFINITION OF MISSION

Recommendation 1-1: As a top management priority, Federal agencies should re-examine the missions of their laboratories with the laboratory directors. The agencies should redefine the missions as necessary to ensure that they are consistent with the appropriate roles for Federal laboratories. The missions must be made sufficiently clear and specific to guide the agencies and the laboratories in setting the goals against which the laboratories' performance can be measured.

PROGRESS SUMMARY

Defining the mission of the laboratories is a difficult task requiring that the agency's mission is clear and that the laboratories receive adequate attention from top management. Some of the agencies and laboratories have missions defined by their statutes (e.g., the National Institutes of Health and the National Bureau of Standards) and believe that unclear mission is not a problem.

All agencies made an effort to implement this recommendation. Most have existing procedures for reviewing their activities, and the report's recommendations were considered in the review processes. Several agencies took additional measures specifically to implement the recommendations.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- The Agricultural Research Service (ARS) developed a long-term research plan identifying areas for increased emphasis for the 1980s as well as research possibilities for the next 20 to 50 years. Such long-term planning had been lacking before. The plan reflects the best thinking of some 500 ARS scientists and members of its National Planning Staff on how ARS can meet the USDA's short- and long-term needs most effectively and efficiently. It will serve to guide the missions and performance evaluation of the ARS laboratories.
- The Administrator of the National Oceanographic and Atmospheric Administration (NOAA) had the mission statements of all the NOAA laboratories and Fisheries Centers revised and updated in response to the report.
- In July 1983, the Secretary of Energy issued the Department's policy guidance on the role and missions of the multiprogram laboratories consistent with the National Energy Policy Plan. In February 1984, the Department of Energy's Laboratory Management Council developed a generic laboratory role statement and reviewed and revised all proposed laboratory mission statements. An established institutional planning process will ensure annual review of laboratory missions projected 5 years into the future.

- The Secretary of Transportation appointed a new Science and Technology Advisor for the Department and directed him to oversee implementation of the report. The operating administrations have evaluated laboratory operations and are instituting changes necessary to ensure consistency with new laboratory mission statements and performance goals. The Department recently completed a study that identified various options for privatizing operation of the Transportation System Center. Discussions on the practicability of these options are ongoing.
- In addition to continually reviewing and revising the mission of its laboratories, the Environmental Protection Agency's Office of Research and Development plans to establish a Strategic Planning Staff whose function will be to study emerging environmental problems and determine: (1) whether research is warranted, (2) where research efforts should be focused, and (3) perhaps even how the research results would relate to current or proposed policy direction. The laboratories' missions will be redefined as necessary to accommodate the research efforts identified by the Strategic Planning Staff.

FUTURE DIRECTIONS

While direct agency response to this recommendation has been good, there obviously is a need to continually re-examine the laboratories' missions. Such activities should be carried out in conjunction with the oversight function discussed under Recommendation 4-1.

SIZE OF LABORATORIES

Recommendation 1-2: The size of each Federal laboratory should be determined by its missions and the quality of its work. That size should be allowed to increase or decrease (to zero, if necessary) depending on mission requirements, but it should not fluctuate randomly. Preservation of the laboratory is not a mission.

PROGRESS SUMMARY

The Panel did not expect that special and immediate actions be taken to implement this recommendation. The agencies have mechanisms established for reviewing the staffing of the laboratories. These reviews have taken place in conjunction with the agencies' annual budget review, which is an acceptable approach as long as the budget allocation reflects careful evaluation of the agencies' missions and performance.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- Recent mission redefinitions in the Department of Energy have resulted in significant decreases in laboratory size in the area of applied technologies, particularly those viewed as having near-term commercial benefits. The Laboratory Management Council, as part of its evaluation of laboratory 5-year institutional plans, will review the proposed size of laboratories based on approved missions.

- In the Department of Transportation, the Federal Aviation Administration's Technical Center has reduced functions not considered essential to the National Airspace System Plan and increased its staffing for testing and evaluation of new computers and automated systems, consistent with the plan. Changes in Administration priorities have also been reflected in the staffing levels and skill mix of the Transportation System Center. The Transportation Test Center of the Federal Railroad Administration has been operated for several years by the private sector; its operators are free to implement staffing adjustments based on anticipated mission requirements.

FUTURE DIRECTIONS

Linking laboratory staffing review to budget reviews assures that the size of the laboratories is re-examined annually. However, it does not assure that this size reflects the missions of the laboratories or the quality of their work, particularly in times of prosperity. The agencies must continue to focus on laboratory missions and quality of work rather than size of the budget. There will always remain external factors affecting laboratory staffing. Also, the creation of new laboratories has not always been based on the agency's determination of need. Decisions to close or consolidate laboratories have been politically difficult and will likely remain so.

2. RESOURCES: PERSONNEL

SCIENTIFIC/TECHNICAL PERSONNEL SYSTEM

Recommendation 2-1: Administrative and legislative actions should be initiated now to create, at government-operated laboratories, a scientific/technical personnel system that is independent of current Civil Service personnel systems. The experimental system for managing scientific and technical personnel at the Naval Weapons Center and Naval Ocean Systems Center is an example of how this can be approached.

PROGRESS SUMMARY

Since this recommendation applies to all agencies with R&D activities, and proposed legislation requires coordination across these agencies, the working group on personnel issues approached it as a joint effort rather than on an agency-by-agency basis. The major achievements of the working group are:

- Development of model legislation;
- Assessment of actions that could and should be taken that do not require legislation;
- An examination of the government-owned, contractor-operated (GOCO) laboratory modus operandi based on the Department of Energy's experience with the GOCO concept; and
- Collection of appropriate statistical information

The proposed legislation is undergoing review at senior levels in the agencies and in the Office of Personnel Management. Actions that do not require legislation have been recommended by the working group and are under consideration by the Office of Science and Technology Policy (OSTP) and the Office of Management and Budget (OMB). Examination of the GOCO option is provided as an alternative to operating the laboratories with Federal Government employees.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- *Key features of draft model personnel legislation.* The legislative model produced by the interagency working group embodies the following concepts:
  - —Permits agencies to establish alternative personnel systems;
  - —Applies to scientific and technical personnel in the Federal laboratories, and to similar personnel throughout an agency if broader coverage is deemed essential to mission accomplishment;
  - —Bases pay on performance rather than on longevity;
  - —Creates broad pay bands;
  - —Simplifies job classification;

—Allows the pay cap to be waived for up to 5% of the covered positions—these uncapped positions are limited to specially qualified scientific and technical personnel;

—Permits the agency head to classify positions and fix compensation so as to make positions competitive with rates and practices for comparable positions outside of the Federal Government;

—Allows the inclusion of positions now in the Senior Executive Service (SES); and

—Permits the Naval Weapons Center and Naval Ocean Systems Center personnel systems to become permanent.

The draft model legislation does not describe a personnel system in great detail. It provides some general guidelines. In spirit, the model legislation is very similar to the demonstration project section (5 USC 4703) of the Civil Service Reform Act of 1978. The model legislation provides the Office of Personnel Management (OPM) and the agencies the authority to develop alternate personnel systems for scientific and technical personnel at Federal laboratories and, under appropriate conditions, outside of Federal laboratories. These systems can be tailored to the peculiar needs of a given agency or of a given laboratory. It is anticipated that any changes in agency personnel systems would be accomplished, over time, within existing budget resources and be the basis for improving the use of those resources.

- *Personnel actions not requiring legislation.* A number of actions were also considered within existing statutory authority to improve the ability of government-operated laboratories to attract, retain, and motivate scientific and technical personnel. Actions recommended by the interagency working group are:

—Exclude laboratories from the current proposal to reduce the number of employees in Civil Service grades 11 through 15; the technical work of the laboratories is performed almost entirely by personnel in grades 11 through 15, and entry into, and promotion within, these grades should be facilitated, not impeded;

—Allocate to the laboratories more positions for specially qualified scientific and technical personnel under provisions of 5 USC 3104, and allow some supervisory responsibility for such positions;

—Provide government-operated laboratories with blanket, permanent direct hire authority for all professional scientific and technical positions in the laboratories;

—Provide government-operated laboratories with blanket, direct hire Excepted Service Appointment Authority for research associates;

—Exempt laboratory summer hires in technical positions from manpower ceilings in order to bring in new ideas and provide a source of potential recruits for laboratory staff positions;

—Include special rate schedules, for engineers and other manpower shortage occupations, in annual cost of living adjustments that are applied to other Federal pay scales; and

—Increase the probationary period for scientific and technical personnel from one year to a more suitable period, such as 3 years.

FUTURE DIRECTIONS

Further consideration of the draft model legislation as a basis for legislation that might be recommended by the Administration needs to reflect the official views of the Office of Personnel Management and the heads of the affected departments and agencies. The appropriate next step would be for OPM to consider the proposed model legislation and, if it concurs, to submit a proposed bill to the Office of Management and Budget for legislative clearance by the affected agencies. This process should be completed by the beginning of the next Congress.

Actions not requiring legislation can be given further consideration by OPM for agency and OMB/Office of Science and Technology Policy review while the model legislation discussed above is under review.

Both legislative and administrative changes in personnel systems for agency laboratories operated with Federal employees will need to be assessed in the review process in light of:

- The extent of the problems faced by the laboratories and the potential impact of changes;
- The effect of special treatment of laboratory personnel on the Civil Service system in general; and
- The impact of legislation and administrative changes on broader Administration efforts to restrict overall Federal employment, to hold down average grades, etc.

SALARY ADMINISTRATION AT CONTRACTOR-OPERATED LABORATORIES

Recommendation 2-2: Contracts governing government-owned, contractor-operated laboratories should be rewritten to permit the contractor to establish and carry out an independent salary administration.

PROGRESS SUMMARY

The Air Force contract with the Massachusetts Institute of Technology does permit the university to establish and carry out an independent salary administration at Lincoln Laboratory. For salaries subject to Department approval, the Department of Energy (DOE) has increased the salary cap on the directors of GOCO laboratories. At the present time, applicable salary actions in excess of $50,000 still require DOE approval. In the case of the Jet Propulsion Laboratory, the National Aeronautics and Space Administration (NASA) reviews annually the average salaries for various categories of employees. DOE and NASA do not require prior approval of GOCO laboratory job offers.

FUTURE DIRECTIONS

DOE is increasing the threshold for salary approvals by $10,000, where applicable, and thereby delegating approval authority to the laboratories for salaries up to $60,000. DOE will review periodically the threshold levels to

ensure that there is no increase in the percentage of total salary actions reviewed by the Department. DOE will also continue to refine and clarify criteria for market basing of salary structures to facilitate the review and approval of periodic salary adjustments with only minimal discussions with the Department.

CONTROL OF MANPOWER LEVELS

Recommendation 2-3: Personnel ceilings at government-operated laboratories should not be used in addition to budgetary control. Federal agencies should provide budget constraints and give the laboratory directors freedom to decide how to meet them. Laboratory directors should also be allowed to make the final decisions on contracting for support services at the laboratories.

PROGRESS SUMMARY

The situation is quite mixed across the government. Most Federally operated laboratories find themselves under some form of personnel ceilings in addition to fiscal constraints. To remain within necessary overall limits on Federal manpower for an entire agency, and to properly carry out responsibilities for overall agency management, agency heads often find it necessary to allocate specific manpower resource levels to subordinate laboratories. In some cases, the personnel ceilings are on the total laboratory population. In other cases, the total number of high grades (GS-13 through 15) have been under a separate ceiling. At times, laboratories have found themselves simultaneously under all of the above constraints. There has been a growing awareness within the Federal agencies that these multiple constraints result in lack of flexibility and the creation of non-productive bureaucratic processes. The final result is often a workforce that is not optimum for the current mission of the laboratory. There is a need, therefore, to strive for a better balance between the controls necessary for agency heads to meet their responsibilities for overall agency management and a Federal laboratory director's need for sufficient flexibility to permit optimum laboratory management.

The Department of Defense industrially funded laboratories are no longer operating under total personnel ceiling control. Other DOD activities and other agencies currently are operating under some form of total ceiling control.

The April 1984 report of the House Armed Services Committee on the Department of Defense Authorization Act, 1985, recommends waiver of civilian personnel ceilings for fiscal year 1985. The report states: "The Committee was greatly encouraged by the results of the industrial fund test. Facing a total workload that was little changed from 1982, industrial fund managers did not significantly expand the overall work force in fiscal year 1983. Thus the most important result of the test is what did not happen—managers, unconstrained by ceilings, did not engage in unwarranted hiring." (p. 246)

FUTURE DIRECTIONS

On the assumption that personnel ceilings for agencies will need to be retained to meet overall Federal employment goals of the Administration, agency heads should allow maximum flexibility to laboratory directors in the control of staffing at laboratories, including the use of contract support personnel.

3. RESOURCES: FUNDING

MULTIYEAR FUNDING FOR R&D

Recommendation 3-1: The Congress and Office of Management and Budget should authorize funding for R&D programs on a predictable multiyear basis so that staffing levels and research activities at Federal laboratories can be properly planned.

PROGRESS SUMMARY

An interagency working group addressed this recommendation as a joint issue since it involved almost all agencies. When the working group examined trends in R&D funding at the agency level, it found that for both basic and applied research, funding is surprisingly stable for most agencies and has shown a steady increase in the past years. However, when agency funding is disaggregated and examined at the component and laboratory level, the fluctuations are larger. In the views of the working group, major factors contributing to these fluctuations are:

- Late Congressional appropriations and agency reviews, and reprogramming actions that cause uncertainty until late in the fiscal year;
- Congressional and Administration changes in focus and areas of interest;
- Continuing resolution authority in lieu of Congressional appropriations; and
- Unpredictable Federal civilian pay raises that have to be paid for out of R&D funds.

Thus, agency operating procedures as well as the appropriation process require modification in order to implement this recommendation.

The interagency working group on funding believes that the Packard Report recommendation can best be implemented if funding for R&D is appropriated on a 2-year basis.

FUTURE DIRECTIONS

Where appropriate, the Administration should encourage Congressional interest in, and actions to provide for, multiyear authorizations and appropriations for R&D programs. In addition, agencies should review their own operating procedures to minimize internally generated uncertainties in funding laboratories.

While improvements in funding and personnel planning and management are the focus of Packard Report recommendations, future thrusts must also include upgrading laboratory facilities and equipment as an appropriate trade-off against operating funds within total available funds. Continuous, rapid changes in the state-of-the-art make it essential that Federal laboratories be equipped with modern buildings and tools.

DISCRETIONARY FUNDS

Recommendation 3-2: At least 5 percent, and up to 10 percent, of the annual funding of the Federal laboratories should be devoted to programs of independent research and development at the laboratory directors' discretion. Federal agencies should establish a mechanism to evaluate the results of such work, with the size and continuation of discretionary funds related to laboratory performance. In order to encourage cooperative research programs, the laboratory directors should have the authority, and be encouraged, to spend part of the discretionary funds at appropriate universities and industries.

PROGRESS SUMMARY

Most agencies reviewed have a discretionary funding program in effect or will institute such a program in the near future. Current status of discretionary funding is:

Agency	*Status*	*Planned Action*
USDA	No explicit discretionary funds	Will establish guidelines to meet recommendation's intent
DOC/NBS	About 6%	None
DOC/NOAA	No explicit discretionary funds	Discretionary funds will be requested as part of future budget initiatives
DOD/Army	10% of basic research None for applied research	None
DOD/Navy	7% of basic research 2% of applied research	Increase to 5% of applied research
DOD/Air Force	7% of basic research None for applied research	Begin 0.5% of applied research in FY 85. Increase to 4% by FY 89
DOE	Up to about 5% in addition to significant flexibility	Implementation of new policy statement with emphasis on results-oriented review
HHS/NIH	All funds considered discretionary	None
DOI/BOM	No explicit discretionary funds	None
DOI/USGS	5-10%	None
DOT	No specific percentage used as guidelines. New policy being reviewed	Policy supporting the recommendation planned for next budget cycle
EPA	No explicit discretionary funds	Laboratory directors will be given greater flexibility in conducting projects
NASA	About 4% excluding salaries	None

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- The Office of Naval Research has agreed to maintain discretionary funds as a constant percentage of basic research funds (about 7%). The Office of Naval Technology has agreed to increase the percentage of discretionary funds as a part of applied research funds (from 2% to about 5%).

- The Air Force currently maintains discretionary funds in basic research equal to 7% of basic research budget. In fiscal year 1985 the Air Force will establish applied research discretionary funds equal to 1/2% of applied research budget, growing to 4% of applied research in fiscal year 1989.
- The Department of Energy issued a policy statement in December 1983 that clearly established policy and uniform guidelines for use of exploratory research and development funds at multiprogram laboratories. Under this policy, laboratories may use a reasonable amount of operating funds for early explorations and exploitation of creative and innovative scientific and technological concepts arising in the course of the laboratory's work. The laboratory directors exercise authority in choosing projects for funding.

FUTURE DIRECTIONS

Where providing more discretionary funds comes as a new concept, and where such funds are in constant competition with directed funding, agencies need to be continually aware of the need to foster independent research, consistent with established overall agency roles and missions, as a means of stimulating innovation.

CARRYOVER FUNDING

Recommendation 3-3: Federal laboratories should be allowed to carry forward remaining funds into the next fiscal year. This would eliminate the wasteful practice of hurried spending at the end of each fiscal year.

PROGRESS SUMMARY

There is a wide variation among agencies in the length of time allowed for obligation of R&D funds. The current status is:

Agency	*Obligation Authority Time Limit*
USDA	1 year
DOC	No time limit
DOD	2 years
DOE	No time limit on R&D appropriations
HHS/NIH	1 year
DOI/BOM	No time limit on research funds
DOI/USGS	1 year
DOT	No time limit
EPA	2 years
NASA	2 years

While the Department of Defense (DOD) has 2-year obligation authority from Congress, agency policy requires that laboratory directors obligate up to 97% of their budgets by the end of the first fiscal year and 100% by the end of the following quarter. Difficulties arising from this approach are further compli-

cated when appropriation action is delayed beyond the start of the fiscal year. No action has been taken by DOD to modify the policy. There are no plans at present on the part of agencies with 1-year authority to ask Congress for more flexibility.

FUTURE DIRECTIONS

Where agency policies cause inflexibility and inefficiencies in the obligation of laboratory funds, the responsible R&D managers must take the initiative in making reforms. Agencies with only 1-year obligation authority must likewise take the initiative in their budget proposals to request a longer period.

4. MANAGEMENT

OVERSIGHT OF LABORATORIES

Recommendation 4-1: For each Federal laboratory, there should be an oversight function responsible for assuring the continuing excellence of the laboratory. This function could be performed by an external committee which should include strong industry and university representation. This committee would spend enough time at the laboratory to become familiar with the laboratory's strengths and weaknesses. It would focus on productivity and on the excellence, relevance, and appropriateness of research. The oversight committee would make recommendations to the agency and inform the laboratory director of these recommendations. Those recommendations would be taken into account by the agency and laboratory in their budget decisions. In addition, the committee would give special attention to reducing micromanagement by the sponsoring agency.

PROGRESS SUMMARY

The Packard Panel did not intend to dictate a single form of oversight for all laboratories in all agencies. The important features sought of this oversight are that (1) it provide a broad, laboratory-wide evaluation, (2) this evaluation go beyond the scientific merit of individual research areas, as is usually the case, to cover the appropriateness of the laboratory work and the management of the laboratory, and (3) the oversight body report to the parent agency rather than the laboratory director alone. Most of the agencies have existing oversight mechanisms that could fulfill the above expectations.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- The National Oceanographic and Atmospheric Administration plans to establish an Advisory Group for the oceanic and atmospheric research laboratories, reporting to the Oceanic and Atmospheric Research Assistant Administrator.
- At the Department of Defense, the Services were requested to form external advisory groups for their laboratories under the aegis of their Scientific Advisory Boards and to provide plans for how these groups would operate to perform the oversight functions. These plans have been submitted to the Secretary of Defense.
- The Army Materiel Development and Readiness Command has initiated an independent assessment of its laboratories using members of the Army Science Board. Peer reviews are to be completed in 1984 at the Army Tank-Automotive Command and at the Army Avionics Research and Development Activity. This peer review process will be institutionalized to cover 4 to 5 laboratories per year. The assessments, scheduled for 3 to 5 days at each laboratory, will review the quality of the staff, facility, and technical program; examine how productive the laboratory is

in accomplishing its mission; and assess how relevant the laboratory's work is to key Army problems.

- The Department of Energy's (DOE's) Laboratory Management Council is working on ways to implement effectively the oversight function appropriate to each laboratory's circumstance, utilizing existing organizations and boards where effective, and modifying processes where necessary. Oversight panels exist for Argonne National Laboratory and Brookhaven National Laboratory; the new Oak Ridge National Laboratory contract includes a provision for an oversight panel. Weapons laboratories have similar panels reporting to the University of California. Plans are being developed to ensure that these groups can and will effectively perform the required oversight functions.

FUTURE DIRECTIONS

Agencies that have not yet established oversight mechanisms need to continue movement in this direction. There are a number of successful models that can be emulated.

COMPETITIVE PEER REVIEW FOR FUNDING LABORATORY BASIC RESEARCH

Recommendation 4-2: Federal agencies should rely to a greater extent on the competitive peer review process for funding basic research at their laboratories.

PROGRESS SUMMARY

Some form of peer review takes place at most laboratories. Additional actions are under way in several agencies to respond to this recommendation.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- The Department of Energy's proposal preparation and approval process within the laboratories has many features comparable to traditional peer review, including extensive review by advisory committees to the laboratories. In addition, DOE has established a working group to propose guidance on how best to accomplish competitive peer review of basic research performed by the laboratories and by universities. The Laboratory Management Council will review the proposed actions and recommend any necessary changes in Departmental policy.

FUTURE DIRECTIONS

The concept of peer review is becoming more widely accepted as a form of competition and quality control. Agencies that have long-established peer review systems must re-examine them periodically to ensure that they are functioning effectively.

APPOINTMENT AND EVALUATION OF LABORATORY DIRECTORS

Recommendation 4-3: The laboratory director must be held accountable for the quality, relevance, and productivity of the laboratory. Appointment of the director should be for a finite term, with the option of extending or abbreviating the term depending on the performance of the director and the laboratory.

PROGRESS SUMMARY

Most of the agencies have government-operated laboratories whose directors are members of the Senior Executive Service (SES). The military directors of the Department of Defense laboratories have 3-year terms. The agencies feel that the SES system provides them with sufficient flexibility. DOE, which principally utilizes GOCO laboratories, has taken action in this area.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- A DOE Order on uniform laboratory appraisal, issued in October 1983, requires annual results-oriented appraisals at all the major multiprogram laboratories, including laboratory director accountability.
- At the National Institutes of Health, a new proposed pay and personnel system recommends renewable terms for laboratory and branch chiefs (5-year terms; after age 70, 1-year terms). One of the institutes has already implemented a policy of appointing new laboratory/branch chiefs to 7-year terms.

FUTURE DIRECTIONS

Even where laboratory directors are in the Senior Executive Service and subject to annual performance appraisals, agencies are beginning to recognize the advantages of having fixed-term appointments. Such appointments establish a planning and performance framework that benefits both the laboratory director and parent agency. Indications are that further progress in the spirit of this recommendation will be made.

REPORTING TO CONGRESS

Recommendation 4-4: The above recommendations apply to all Federal agencies. The management of the Department of Energy presents an additional special problem, and the Panel recommends that the Administration and Congress work together to stabilize and strengthen DOE management and to define and affirm its mission. Congress should also refocus its oversight of DOE R&D into a significantly smaller number of committees.

PROGRESS SUMMARY

Compared to other departments, DOE has undergone the most changes in missions in the past 5 years, evolving from the Atomic Energy Commission to the Energy Research and Development Administration/Federal Energy Ad-

ministration to DOE. Recent reductions in near-term renewable energy, and demonstration and commercialization activities, coupled with the Secretary of Energy's statement on Federal and DOE laboratories' roles, have put the Department in the best position to date to communicate and affirm DOE missions and to participate in discussions with Congress regarding simplifying or refocusing legislative oversight of the Department's research and development.

5. INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

ACCESS TO FEDERAL LABORATORIES

Recommendation 5-1: Federal laboratories should encourage much more access to their facilities by universities and industry.

PROGRESS SUMMARY

Implementation has been strong and widespread. Some Federal laboratories have a long tradition of providing access to their facilities and have already compiled an outstanding record of achievement. Many others are displaying a renewed commitment to this goal and are making good progress toward attaining their individual objectives. A primary reason for this progress is the fact that provision of access to facilities lies almost entirely within the jurisdiction and the means of the laboratories themselves.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- *New construction of joint facilities.* The Department of Commerce's National Bureau of Standards has teamed with the University of Maryland and the Montgomery County Government to form the Center for Advanced Research in Biotechnology. Scientists from academia, industry, and government will conduct joint research in this laboratory to be built by Montgomery County on land donated by a private foundation. The Department of Agriculture's Beltsville Agricultural Research Center will also participate in research at the Center.
- *Support to education.* The Department of Defense (DOD)-sponsored High School Science and Engineering Apprenticeship program has, over the past 4 years, given more than 2,000 young people the opportunity for summer research in DOD laboratories or with university researchers under contract to DOD. Summer research programs in DOD laboratories support approximately 50 graduate students and 300 university faculty members each year. In 1984, DOD will test a new program to give summer research experiences to high school teachers of science and mathematics.
- *Facilities directory.* A "User's Guide to Department of Energy (DOE) Facilities" was published in January 1984 to provide information about unique laboratory facilities and equipment available to industry and universities for conducting their own research on-site at the laboratories using equipment available only at DOE laboratories. In addition, about 5,000 students and university faculty will participate in DOE-sponsored research and training programs at the laboratories in 1984.
- *Facilities for advanced training.* In collaboration with The Johns Hopkins University, the Foundation for Advanced Education in the Sciences at the National Institutes of Health supports a program that permits Ph.D.

students enrolled at Johns Hopkins to carry out advanced thesis research under NIH supervision.

- *Interaction with universities.* The Department of the Interior maintains strong, two-way ties with universities through the U.S. Geological Survey (USGS) and the Bureau of Mines (BOM). USGS graduate internships are awarded to some 30 research students yearly, and over 50 USGS scientists serve as adjunct professors at universities around the country. Most BOM laboratories are located close to university campuses; cooperative agreements are in effect with seven universities for fellowships or for the sharing of facilities. Plans are now under way for a USGS lecture program at historically Black colleges and universities. In the Department of Commerce, the National Oceanic and Atmospheric Administration's (NOAA's) Environmental Research Laboratories and Fisheries Centers are located on or near campuses of major universities. Long-term agreements in the form of cooperative institutes have been established between NOAA and several of these universities.

- *Space Shuttle launches as forum for education.* The National Aeronautics and Space Administration (NASA) has supported five conferences for "Distinguished Educators" at Shuttle launches, each targeted at specific segments of the educational community offering high-impact opportunities. These include women and minorities, science and technology, elementary education, and physics training. The conferences provide curriculum supplements and skills development for elementary and secondary school teachers and university faculty.

- *Visiting scientist programs.* In addition to on-going activities aimed at encouraging university and industry access to their facilities, the Environmental Protection Agency (EPA) recently implemented a new "Senior Visiting Scientists" program. This program is designed to bring some of the leading names in environmental science from universities and other institutions into EPA laboratories to conduct research. These scientists will help promote those areas of environmental science that are most significant to the Agency, and the program will help build closer working relationships between EPA laboratories and leading environmental scientists. At the Department of Commerce, a substantial number of leading senior scientists are also brought into NOAA's research activities.

FUTURE DIRECTIONS

While there is much ongoing activity and a heightened awareness of the need for more access to Federal laboratory facilities by universities and industry, more can be done. Specific recommendations for further action within overall agency manpower ceilings and budgetary constraints are:

- Seek ways to expand current programs that provide students and faculty with opportunities to work in Federal laboratories, particularly cooperative job programs and summer jobs for high school and college students;

- Expand current programs aimed at increasing interchanges among university and laboratory personnel, especially those that bring career laboratory staff to university and other educational environments; and

- Consider legislative action to permit continuity of pension plans for scientists and engineers who move between Federal laboratories and universities.

R&D INTERACTIONS

Recommendation 5-2: R&D interactions between Federal laboratories and industry should be greatly increased by more exchange of knowledge and personnel, collaborative projects, and industry funding of laboratory work, provided an oversight mechanism is established to prevent unfair competitive practices.

PROGRESS SUMMARY

Many instances of technology transfer from Federal laboratories to industry already exist, and some of them are crucial components of national technology, contributing positively to our international balance of payments. On the other hand, more can and should be done in this area. Progress toward promoting more R&D interaction with industry has been less apparent and more uneven than in the case of providing greater access to laboratory facilities. However, implementation of Recommendation 5-2 has been impeded by substantive legal and policy issues lying outside laboratory jurisdiction and control, such as government patent policy and the details of enabling legislation. Many such issues are now being addressed by the Department of Commerce, which has lead responsibility for implementation of the Stevenson-Wydler Technology Innovation Act of 1980. Additional helpful proposals have been prepared by the Department of Energy in response to the 1982 study of DOE multiprogram laboratories by the Energy Research Advisory Board. These two developments, together with the influence of the Packard Report, have produced a renewed commitment by Federal laboratories to help increase our industrial competitiveness.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- *Private sector utilization of DOD-developed equipment.* In May 1984, the Assistant Secretary of the Army for Research, Development and Acquisition signed landmark licensing agreements with two industrial corporations to manufacture products developed by in-house research programs at the U.S. Army Construction Engineering Research Laboratory. The two products, a ceramic anode used in corrosion protection and a weld quality monitor, are not military-unique hardware but have wide application in the construction field. The licensing agreement provides for commercialization of the products, with royalties paid to the Government for sales to the private sector.
- *Improving technology transfer mechanisms.* One of the more effective technology transfer mechanisms is the use of person-to-person interactions. In this way, the knowledge of scientists, engineers, and inventors about products and processes is directly coupled to individuals in other sectors of the economy whose skills and interest lie in the development of those products and processes for the marketplace. Involvement by labo-

57-279 O - 87 - 57

ratory staff members is not only a means of implementing this principle, but it can also contribute to professional development of the individuals involved. The Department of Energy has informed the directors of its multiprogram laboratories that the Department's policy is to encourage technology transfer, consulting arrangements between laboratory employees and the private sector, and improved relations with industry. To facilitate these efforts, DOE has issued a class patent waiver policy for inventions arising from reimbursable work for others and for work at DOE user facilities.

- *Speeding delivery of research discoveries to users.* The Department of Agriculture is implementing a new plan for technology transfer that involves a newly appointed national technology transfer coordinator and a nationwide computer network. The network will transmit current research information from Federally sponsored researchers to computer terminals at land-grant universities and other users in all 50 states.

- *Expanding interaction with industry.* The National Bureau of Standards plans to double (to about 200) the number of industrial research associates working in its laboratories. Additional collaborations with industry include automated manufacturing, electronics, computer standards, and several projects in materials science. A proposal to upgrade the research reactor includes dedicating one-third of the new ports to industrial use. The Bureau received approval from the Department of Commerce in May 1984 to allow use of selected facilities by the private sector for proprietary research.

- *Sharing of health-care technology with industry.* The National Institutes of Health have formed a Committee on Joint NIH-Private Sector Endeavors to promote collaboration with commercial organizations and speed two-way technology transfer. Through July 1983, some 54 non-exclusive licenses and an additional 10 exclusive licenses were granted to industry for patented inventions made in NIH laboratories. Conversely, a recent agreement between the National Cancer Institute and an industrial biotechnology firm will permit NCI to explore industrially developed technology in Federal cancer research programs.

- *Federal technology for pollution control.* The Environmental Protection Agency has established collaborative programs with industry as a major component of the EPA research program to develop pollution-control systems. The products produced by this government-industry partnership include fabric filters, limestone injection scrubbers, sequencing batch reactors, mobile waste treatment facilities, and hazardous-waste disposal techniques.

- *Increasing the availability of data to industry and the public.* NOAA's Space Environment Research Laboratory has recently initiated a contract with a private company to provide real-time solar data and forecasts to the public over WEST STAR 4 satellites. Doppler radar and lightning information gathered by the National Severe Storms Laboratory is being sent in real time via the National Weather Service to local broadcasters.

- *Development and application of carbon-fiber composite materials to replace aluminum in aircraft.* NASA laboratories were instrumental in

developing carbon-fiber composite materials, offering direction-tailored strength equal to that of aluminum at less weight, for flight-critical components of commercial aircraft designs. Three major aerospace firms participate with the NASA laboratories in continuing refinements of this technology and will validate its use for very large wing-box and fuselage structures this year. Several general-aviation aircraft incorporating this technology should attain Federal Aviation Administration flight worthiness certification in 1985.

FUTURE DIRECTIONS

The varied origins and missions of the laboratories have resulted in different degrees of involvement with industry. In some cases, close collaboration with industry has always been part of day-to-day operations. In others, it is a fairly new concept, and some deep-seated institutional attitudes need to be modified. Further actions that need to be taken, for example, are:

- Where it is not stated explicitly, incorporate contribution to U.S. industrial competitiveness as a laboratory mission;
- Formalize the authority of laboratories to enter into cooperative research projects with industry, universities, and non-profit organizations;
- Extend the authority of government-operated laboratories to grant patent rights to private sector organizations in order to encourage external cooperation in Federal laboratory research;
- Establish guidelines for Federal laboratories concerning technology transfer to foreign organizations; and
- Maintain focus on R&D appropriate for Federal support so as to not overtake the role of the private sector in pursuing commercial opportunities created by Federally sponsored research.

FEDERAL PROCUREMENT PROCEDURES

Recommendation 5-3: Contracting by agencies and laboratories for universities and industry to conduct R&D should be encouraged by simplifying the necessary Federal procurement procedures. The procurement process should give laboratory directors greater flexibility in contracting.

PROGRESS SUMMARY

Only limited progress has been made by individual laboratories in implementing this recommendation, since revision of Federal procurement procedures lies almost completely beyond the control of the laboratories themselves and largely beyond the control of entire agencies. The time required to award a contract for basic research continues to increase in most agencies. The remedial action required is government-wide in scope, and enormously complex. Fortunately, there is promise of improvement in response to recommendations of a November 1983 report of the National Academy of Public Administration (*Revitalizing Federal Management: Managers and Their Overburdened Systems*, Chapter 4). These recommenda-

tions are widely supported by Federal procurement executives and appear to offer the best available approach to continued, systematic progress in this area.

Achieving a procurement policy that is both equitable and efficient requires a balance between measures to ensure adequate competition and procedures that allow timely and flexible action by laboratory managers. Recent actions by both the Executive and Legislative branches have expanded measures to ensure increased competition for Federal contract awards, particularly through restrictions on accepting unsolicited proposals and discouraging sole source contracts. However, these actions may also reduce the flexibility and timeliness of contracting for basic research with universities and industry.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- *Simplifying procedures for contracting with universities.* The Department of Energy has established a working group to recommend ways to simplify contracting procedures for university research. As part of this process, DOE is converting many university awards from contracts to grants. Also, emphasis has been placed on consistent interpretation of DOE university procurement regulations and procedures by all field elements.

FUTURE DIRECTIONS

Difficulties with the Federal procurement process are not going to be overcome in a short time. Progress in this area requires continuing and relentless effort on the part of both the government and the private sector.

The peer-review system, long used by the scientific research community to ensure the relevance and worth of unsolicited research proposals, is a form of competition, albeit one operating very differently from the price competition appropriate to military hardware acquisitions. This fact needs to be more widely understood and supported within the government.

Some specific actions that need to be taken by the Federal Government are:

- Continue support of the recommendations contained in Chapter 4 of the 1983 report, *Revitalizing Federal Managment: Managers and Their Overburdened Systems*, which are aimed at a systematic reduction in the complexity of Federal procurement regulations;
- Ensure that legislation and executive orders designed to increase competition for Federal contract awards do not hinder the procurement of unique and innovative basic research, particularly through rapid response to unsolicited proposals;
- Recognize the peer review system as a form of selection appropriate to the procurement of basic scientific research, and hence satisfying the concern for competition in procurement now prevalent within government; and

- Establish the following objectives for all agencies in funding basic research:
  (1) Encourage concise proposals (usually under 15 pages) depending on the complexity and size of the project;
  (2) Safeguard the technical proposal as property of the proposer; and
  (3) Make award or reject within 6 months of proposal receipt.

SUPPORT TO MILITARY OPERATING FORCES

Recommendation 5-4: Support to the military operating forces should be an important criterion among others for measuring performance at the DOD laboratories.

PROGRESS SUMMARY

Each of the Armed Services has means for both formal and informal communication between the DOD laboratories and the operating forces. The more formal procedures ensure that operational needs are incorporated into laboratory plans through the budgetary process and are prioritized within available resources. The less formal procedures apply laboratory capabilities to meet the urgent technical needs of the operating forces.

A task force formed by the Office of the Secretary of Defense is considering new approaches to provide closer coupling of the Service laboratories with the operating forces. The task force has identified a number of Service programs wherein the laboratories provide support to the operating forces.

SELECTED HIGHLIGHTS OF AGENCY ACCOMPLISHMENTS

- The Army Materiel and Readiness Command (DARCOM) has a number of programs to identify requirements for R&D support of the operating commands. Teams of DARCOM scientists regularly conduct fact-finding missions to field units for the purpose of identifying problems in the operational use of communications equipment that require R&D solutions. DARCOM maintains 19 detachments of on-site liaison representatives at Army training centers and schools to identify problems requiring R&D support. These needs are communicated directly to the appropriate DARCOM laboratories.
- The Naval Material Command co-locates approximately 30 scientists and engineers on a rotating basis with their operational commands under the Navy Science Assistance Program. The rotational assignments provide the scientists and engineers with operational experience and improve communications with the laboratories in operational problems.
- The Air Force has a variety of procedures for identifying the R&D needs of the operating commands. Formal documents to identify logistics needs, research needs, and R&D objectives are developed through cooperation among Air Force Logistics Command, Air Force Systems Command, and the operational commands. The Strategic Air Command hosts an annual, week-long conference with laboratory participants to identify R&D

objectives and to foster informal cooperation. The Tactical Air Command has a point of contact for each development program element and is consulted for comments on relevant exploratory and advanced development programs. The Chief Scientist of the Air Force has initiated a program whereby the Chief Scientists of Air Force organizations meet semi-annually at locations of the operating forces. The goal of these meetings is to enhance interactions between the operating forces and the Air Force R&D community.

FUTURE DIRECTIONS

The DOD plans to form external advisory groups for its laboratories under the aegis of the Services' Scientific Advisory Boards. These external advisory groups will be asked to include support of operating forces among the important criteria against which they measure the performance of the DOD laboratories.

APPENDIX A

THE WHITE HOUSE

WASHINGTON

August 5, 1983

MEMORANDUM TO THE HEADS OF DEPARTMENTS AND AGENCIES

SUBJECT: Report of the White House Science Council Federal Laboratory Review Panel

The White House Science Council has recently completed a review of Federal laboratories. The report of that review notes that our Federal laboratories have great potential but that they could play a far greater role in meeting national needs if certain management and operating improvements can be made.

As we enter an era of increasing dependence on our science and technology, it is essential that we make better use of our Federal laboratories. I am directing the Office of Science and Technology Policy (OSTP) and the Office of Management and Budget (OMB) to lead an interagency effort to respond to the central thrust of the report.

A report on actions taken by the agencies in this effort should be presented to me by OSTP and OMB no later than July 1, 1984. Agency heads with responsibilities for Federal laboratories are directed to work with these offices in addressing the Science Council's recommendations.

DEPARTMENT OF AGRICULTURE

MISSION

Recommendation 1-1: Mission Review

In February 1983, the Agricultural Research Service (ARS) announced new directions for agricultural research in the 1980s with emphasis on research on critical national needs up to 1990 and projected over the next 20 to 50 years. Some 500 ARS scientists and members of the National Program Staff (NPS) were asked to devise a strategy that would provide, through research, the means by which U.S. agriculture could meet these needs. In response, they developed a document, the ARS Program Plan. The plan records the best thinking of these scientists and NPS members on how ARS can meet the Department of Agriculture's (USDA's) short- and long-term needs most effectively and efficiently.

ARS is redirecting its scientific talent and resources in line with Secretary of Agriculture Block's policy to focus research on national goals. The ARS is projecting that $75 million of its current budget be redirected over 6 years, from 1984 to 1990. A revised program of Forest Service (FS) research under the provisions of the Renewable Resources Planning Act is now in preparation and will be submitted in December 1984.

Recommendation 1-2: Size of Laboratory

The Program Plan includes programs for meeting future, as well as present, needs of U.S. agriculture. On the basis of recommendations by the scientists and the NPS, and guided by USDA policies, a 6-Year Implementation Plan was prepared. In it are identified the programs of highest priority that ARS will support first. The projected resource allocations for those high-priority research programs are being developed. This information will guide decision making by management at all levels in ARS. Programs will be evaluated systematically to identify areas of significant progress, major constraints to further progress, emerging research problems and opportunities, and research that can be discontinued.

The ARS continues to seek ways to improve the efficient use of its facilities and to give increasing emphasis to the optimum use of facilities as redirections prescribed in the 6-Year Implementation Plan are carried out.

The total Forest Service research program is reviewed annually, and assignments to the eight Regional Forest and Range Experiment Stations and the Forest Products Laboratory (Madison, Wisconsin) are adjusted in accordance with long-range research plans and Congressional action.

FUNDING

Recommendation 3-1: Multiyear Funding

From 1975 through 1984, the Agricultural Research Service received steady increases from $218 million to $453 million. In constant 1984

dollars, the increase was from $425 to $466 million. During that time, yearly effort was approximately constant at 2,800 scientist-years while total employment decreased from 9,350 to 8,546. Thus, stable funding appears to have been provided. However, late funding of pay raises caused a significant impact on planning. The USDA's experimental research organizations are primarily in-house with salary costs typically ranging from 65% to 85% of total funds available. A 5% pay raise that must be funded from nonsalary funds reduces those funds from 9% to 28%. Current timing of pay raise decisions requires fundholders to "set aside" those amounts, often until one-half to three-quarters of the fiscal year is over, before they can make final funding decisions. Late appropriations cause similar uncertainties which impact final decisions.

The primary Federal research laboratories in the USDA are in the Agricultural Research Service and the Forest Service. Both receive appropriations directly with no "overhead" taken at the Department level. Both agencies have planning systems that enable proper, predictable multiyear planning except for the impact of late appropriations and unfunded or partially funded pay raises. Neither agency has the flexibility to "absorb" unfunded pay raises except from all other funds that directly affect planned experiments. Thus, the USDA supports the recommendation. If a 2-year budget is not appropriated, full funding of pay raises and a 2-year budget or carry-over authority of unobligated funds would greatly contribute to the proper planning of the Department's research efforts. Full funding of pay raises is by far the most critical aspect, followed by a 2-year budget or carry-over authority.

The Office of Management and Budget (OMB) must request and Congress must fund pay raises; Congress must grant carry-over authority and appropriate funds accordingly, or Congress must appropriate a 2-year budget. If government-wide authority is not obtained, the appropriation committees of the Congress will be requested to fully fund all pay raises for personnel in the Department.

Recommendation 3-2: Discretionary Funds

The USDA laboratories do not have any formal discretionary funds. USDA Federal laboratory directors, however, have authority to decide the subject matter and methodology of research activities and, in exercising this authority, have some freedom to undertake exploratory research. As a result, the decision making authority of USDA managers allows for a degree of discretionary use of funds. The only review of these discretionary decisions occurs in general program reviews or in managers' performance ratings.

The Department supports the recommendation but believes it can accomplish the intent without establishing a formal discretionary fund. A policy statement will be issued by agency heads on the equivalence to formal discretionary funding authority of 1) determining research goals and approaches, and 2) freedom to do exploratory research. The statement will also establish guidelines on the amount of permitted exploratory

research and a review system so that the amount of equivalent discretionary funding authority can be raised or lowered depending on the effectiveness of its use.

USDA will charge appropriate staff or a special committee in the Forest Service and Agricultural Research Service to develop the policy statements. After appropriate review, the Chief of the Forest Service and Administrator of the Agricultural Research Service will issue the policy statements.

Selected Department officials have been briefed on the concept and have concurred in the general approach.

Recommendation 3-3: Carry-Over Funding

P.L. 95307, "The Forest and Rangeland Renewable Resources Research Act of 1978," provides basic guidance to Forest Service research. Section 7 of this Act states, "There are hereby authorized to be appropriated annually such sums as may be needed to implement this Act. Funds appropriated under this Act shall remain available until expended." However, this authority has never been extended by Congress to the Forest Service during the annual appropriation process. Therefore, to date, Forest Service research funds have been appropriated only as annual funds. The Agricultural Research Service has no authority to carry over unobligated funds except for construction and rare special programs of a temporary nature.

The USDA supports the recommendation. If the predictable funding recommendation is not implemented (2-year budget), the Department will request that a minimum of a 120-day grace period be permitted to carry over expiring appropriations.

If the predictable funding recommendation is implemented, no action is required. If not, the Department must request carry-over authority through OMB, and the Congressional appropriation committees must grant carry-over authority.

MANAGEMENT

Recommendation 4-1: Oversight Function

ARS reviews each research project at least once every 3 years. Review panels include research leaders from the laboratories under review and scientists from other government agencies, the academic community, and industry. The review and evaluation of research programs at many levels in ARS serve to identify areas of significant progress, major constraints to further progress, emerging research problems and opportunities, and research that can be discontinued. That information is used in setting priorities, planning and implementing redirection, developing budgets, and revising the 6-Year Implementation Plan and the operational plans. The National Program Staff is responsible for reviewing national programs and for evaluating their progress and consistency with the 6-Year Plan.

A continuing schedule of technical review of Forest Service research units monitors performance and productivity. These reviews include peer specialists from universities, private industry, and state forest agencies.

Recommendation 4-2: Greater Reliance on Peer Review

A system is in place that provides for peer review of each research project before implementation.

In the application of the Research Grade-Evaluation Guide, grade levels for scientific positions are determined by committees (often referred to as peer panels) rather than by a single classification specialist—the usual practice in the Federal Government. Scientists prepare written material describing their research assignments and their accomplishments, and an appropriate panel periodically reviews the position. Panels consist of a committee chairperson (usually a research manager), an executive secretary (a classification specialist), and five scientists.

The peer review and evaluation systems will be reviewed periodically and revised when necessary.

Recommendation 4-3: Finite Term for Laboratory Director

Funds are appropriated by Congress for specific research programs. ARS headquarters allocates those funds to Area Directors (AD's). Each AD is responsible for controlling allocated funds and for assuring that the research program is carried out. Performance of ARS managers is evaluated annually.

A major reorganization of ARS has just been put in place that reduces the number of AD's to 11, (one of whom is director of the Beltsville Agricultural Research Center), eliminates one layer of administrative management, and provides for more direct interaction between research managers in the field and the National Program Staff at Headquarters. The AD's have primary responsibility for the quality of their research programs and work with the NPS in assuring program relevance and conformity with the ARS Program Plan and 6-Year Implementation Plan. The AD's are formally evaluated annually for their effectiveness in fulfilling these responsibilities, and, as members of the Senior Executive Service (SES), they can be reassigned as appropriate to improve program leadership and management.

Forest Service funds are appropriated annually by Congress for specific research subjects as enumerated in the Renewable Resources Research Act of 1978. These funds are allocated to the eight regional experiment stations and the Forest Products Laboratory (FPL) pursuant to their assigned missions and respective roles in the total FS research program. Like AD's, FS experiment station and FPL directors are in the SES.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

In 1983, USDA issued a Departmental Regulation on Research and Education Policy which states that it is the policy of the Department to:

". . . enhance and preserve partnership relations among research and education performers within the total State, Federal and private system."

USDA policy and practice have always been to promote access to research laboratories. This has been successful. For example, in 1981-1982, approximately 2,000 persons visited nine Agricultural Research Service laboratories seeking information and scientific advice. Joint use of equipment and facilities by university and USDA personnel is also practiced at numerous locations—about 50 percent of ARS scientists are located at or adjacent to university facilities. ARS scientists devoted approximately 3.6 percent of their time in 1983 to make more than 60,000 contracts with users of ARS research results. These users included action and regulatory agencies, extension services, farmers and ranchers, agricultural industry, state and local governments, and consumer groups.

Forest Service research results are communicated by means of technical publications, articles in scientific and user journals, workshops, and responses by scientists to individual requests for technical information. Since much of the research is used in the management of the 191 million acres of National Forests, particular attention is given to internal communication of research results within the Forest Service. This takes many forms, including workshops and preparation of concise management guides based on research findings. The State and Private Forestry Branch of the FS has the responsibility to supplement the technology transfer of applied research to the state forest land management agencies and to private forest landowners. This is done through technical meetings, special workshops, and joint efforts with state forestry agencies and others. In total, FS technology transfer utilizes a variety of avenues to communicate research results to the scientific community, within the agency itself, and to other research users. Also, forestry research cooperation with university and private sectors is fostered through joint research planning between the FS, the Cooperative State Research Service, and the Association of State College and University Forestry Research Organizations.

Published technology transfer plans are in place to broaden the clientele accessing USDA laboratories. Included will be targeted groups, such as Small Business Development Centers.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

Many USDA researchers maintain close rapport with representatives of industrial firms relevant to their research. This interaction is encouraged and taken into account as part of the scientists' evaluations. At other levels, industry representatives serve in many formal and informal

advisory roles to departmental, agency, and program managers. Industry groups also contract with USDA agencies to conduct specialized research projects within established guidelines. In 1983, ARS scientists made an estimated 15,000 contacts with industry personnel to plan and conduct research and to transfer technology.

Funds allocated by USDA for competitive research grants total $17 million in fiscal year 1984. All universities and industrial R&D organizations are eligible to compete for these grants. Increased utilization of sabbatical assignments and non-competitive temporary Federal appointments will be explored for increasing exchange of personnel between USDA and industry.

DEPARTMENT OF COMMERCE:
NATIONAL BUREAU OF STANDARDS (NBS)
NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION (NOAA)

MISSION

Recommendation 1-1: Mission Review

NBS:

The Department of Commerce (DOC) held strategic Planning Reviews for the National Bureau of Standards (NBS) in September 1982. The NBS mission was thoroughly reviewed and the programs were grouped in three categories: providing a basis for measurements throughout the United States; providing technical assistance to the Federal Government as mandated by Organic Act or legislative assignments; and assisting in solving technological problems that are measurement and test-method intensive.

NBS receives authorization each year by separate Act of Congress. Its mission is therefore updated annually. In addition, NBS testified at Congressional hearings on the NBS Organic Act held in June 1981. The hearings were held "to examine how well the Bureau's present charter serves present needs and covers the activities actually performed by the Bureau; and to determine how the Bureau can and should serve these and other Federal and national needs for research and development by government, industry, and the universities in future years." Following the hearings, DOC/NBS prepared a revised version of the Organic Act for consideration by Congress. The draft clarifies and modernizes the basic functions and activities of NBS.

NOAA:

In the fall of 1982, the Administrator of the National Oceanic and Atmospheric Administration (NOAA) initiated a long-term planning process, the first step of which included consideration of roles appropriate to Federal laboratories and the Federal Government. National needs were listed, and from these candidates future programs and activities were recommended. In response to the report of the White House Science Council's Federal Laboratory Review Panel, the Administrator had the mission statements of all NOAA laboratories and Fisheries Centers revised and updated. The Administrator also conducts, over a cycle of about 18 months, reviews of program areas (e.g., marine quality, marine resources, etc.) that involve more than one laboratory and organization element within NOAA. These reviews are part of the basis used for reassigning responsibilities and priorities within the agency.

Recommendation 1-2: Size of Laboratory

NBS:

Compared with similar laboratories in other industrialized countries, NBS is substantially smaller relative to the size of Gross National Product. In

addition to those activities defined under the Organic Act, NBS has been assigned 22 Congressionally mandated programs. NBS is rebuilding the basic competence that has been eroded due to combined budgetary and personnel constraints and added Congressionally mandated programs. A competence building program initiated in fiscal year 1979 and continued through fiscal year 1983 is currently funded at $7.0 million/year.

The institutional planning process of the Department of Commerce during the budget formulation and review process and the strategic planning objective exercises—coupled with external review processes by peer groups, Statutory Visiting Committee and Evaluation Panels—ensure the quality, importance, and priority of programs, quality of staff, equipment needs, finances, and appropriateness of the program to NBS mission. In addition, the Director and heads of the major operating units reprogram resources to answer the identified priority needs of science and technology. This reprogramming has resulted in a 40% turnover in NBS projects during the last 5 fiscal years.

NOAA:

NOAA has produced a draft long-range plan for research which is to be updated annually. The planning process begins with an analysis of national needs, of the appropriate Federal role in meeting them, and of NOAA's responsibilities. The Administrator makes program direction decisions on the basis of options in the plan, and these are promulgated to the laboratories with relevant missions. The funding and personnel allotments are adjusted accordingly after Congressional appropriations.

As a result of this DOC/NOAA process, the size of the laboratories is adjusted automatically each fiscal year to be compatible with the funding approved by the President and appropriated by Congress for their respective program areas.

FUNDING

Recommendation 3-1: Multiyear Funding

NBS:

NBS receives separate designated appropriations from Congress. NBS currently has appropriations for a 1-year period with unlimited carryover authority.

NBS supports R&D funding on a 2-year basis if that funding is predictable. The appropriation would have to allow for increases for pay raises, cost of living allowances, and supplementals for unforeseen circumstances of a significant nature.

All Congressional authorizing and appropriations committees would have to approve the changes. Departmental and Office of Management and Budget (OMB) policies would have to be brought into line with this method of funding.

NOAA:

Funds are appropriated on an annual basis, with no separate appropriation for research. Base budget is very stable at the laboratory level.

Instability due to annual appropriation is not a problem. No recommendation is made for multiyear funding or for a separate research appropriation.

Recommendation 3-2: Discretionary Funds

NBS:

NBS currently has "competence funding" for use in the long-term research mission. This can be considered discretionary funding, and constitutes 7% of total funds. These funds are used to develop research competence in areas that management views as potentially important in the long-term mission of NBS. The use of these funds is reviewed by the National Academy of Sciences (NAS). NBS has full liberty to execute its program as it deems appropriate, whether in-house or contracted through academia or industry.

No change in funding is necessary to meet the recommendation.

NOAA:

NOAA laboratories currently have no discretionary funds. If urgent needs for new programs on the frontiers of science arise, the agency will reprogram to make funds available. Provisions for discretionary funds would be helpful in meeting this recommendation.

NOAA will request discretionary funds as part of future budget initiatives.

Recommendation 3-3: Carry-over Funding

NBS:

NBS currently has carry-over funding authority.

NBS concurs in need for carry-over authority. Many programs that are delayed need carry-over authority to properly fund the completion of the mission.

NOAA:

NOAA has no-year funds, with no restriction on obligation rates. No change in funding is necessary to meet the recommendation.

MANAGEMENT

Recommendation 4-1: Oversight Function

NBS:

NBS reports its program annually to a two-tiered external oversight function: the Statutory Visiting Committee appointed by and reporting to the Secretary of Commerce and, for each technical program, a Board of Assessments administered by the National Academy of Sciences. During 1981, Secretary Baldridge requested a critical review of all advisory committees within the Department to determine which ones could be terminated. The review covered a total of 89 committees and considered funds expended and products produced. None of the committees was terminated. However, several cost reduction measures were put into place. The formation of another advisory committee appears inconsistent with the

Secretary's actions. Moreover, a proposed Project Evaluation Committee (as recommended in the Grace Commission Report) is redundant with the existing Visiting Committee/Evaluation Panel structure and would be an unnecessary duplication of effort.

NOAA:

NOAA conducts regular reviews both of laboratories and of program areas. Members of industry, academia, and user groups are represented on the review committees. These members are invited on a case-by-case basis. In response to the report of the White House Science Council's Federal Laboratory Review Panel, the process of including outside reviewers and requesting their written reviews has been documented and formalized. The National Marine Fisheries Service (NMFS) is also subject to external oversight by two formally established advisory committees which scrutinize the quality and relevance of the laboratories' activities. These are the National Committee on Oceans and Atmosphere (NACOA), which has oversight for all of NOAA, and the Marine Fisheries Advisory Committee (MFAC), which has oversight for the NMFS. The question of external reviews was discussed at the NMFS Research Council in May 1984, and it was decided that the present system is adequate and that additional processes for accomplishing external oversight are not needed. Plans are to establish a group of advisors to review both the laboratory programs and the research programs across NOAA line organizations.

Recommendation 4-2: Greater Reliance on Peer Review

NBS:

Continuous peer review of NBS activities is assured by a variety of methods.

The Director and the major operating units use the annual reports of the Statutory Visiting Committee and NAS-administered Board of Assessments of NBS programs to assess fundamental long-range research plans and activities. This research must satisfy one or more of the following criteria: furthers the development of standards, data and/or measuring techniques; serves a national need such as defense; answers a technological need.

Industrial, academic, and standards groups advise NBS on technological, measurement, and data needs.

NBS uses advice from ad-hoc industrial, government, and academic groups in assessing its future role in specific long-range research initiatives.

An internal peer review process is used to target new areas of fundamental research for competence building. The advice of outside scientists is also sought as to the merits of these proposed long-range fundamental research programs.

The planning of large facilities (e.g., cold neutron facility and cw-accelerator) to meet the needs of industry, academia, and other government agencies is accomplished in coordination with potential user groups

and other interested parties (e.g., the National Science Foundation, the Office of Science and Technology Policy,and the Department of Energy).

NOAA:

Peer review has always been accomplished to a significant degree, and by the usual processes, i.e., of publication in peer-reviewed scientific journals, attendance and presentation at professional meetings, interaction with other scientists in committees and working groups, and exchanges of personnel. However, feedback has not been assured in all cases. Partly as a result of the White House Science Council's report, the NOAA Administrator has had his personal staff investigate the peer review process in NOAA. The outside review process will be strengthened by giving the outside reviewers of both laboratories and program areas a written charge and obtaining written feedback. In addition, a small "board of visitors" will assist the Assistant Administrator for Research to provide advice and broad overview.

Recommendation 4-3: Finite Term for Laboratory Director

NBS:

DOC has instituted a management by objectives system by which an agreed upon set of strategic planning objectives (SPO's) with their specific measurable milestones constitutes the individual performance plan of the NBS Director. As a Presidential appointee, the Director's tenure will continue to be at the pleasure of the President, and his performance will be evaluated on a regular basis by the Visiting Committee and by the Secretary of Commerce. The Director will be held accountable in fiscal year 1984 by the Secretary of Commerce for the accomplishment of a set of 10 SPO's, each of which has a number of milestones with measurable outputs.

NOAA:

Laboratory and Fisheries Center directors are members of the Federal Senior Executive Service (SES), serving under contracts reviewed twice a year. These contracts require adherence to predetermined standards in laboratory performance. The SES contract and review process thus provides the opportunity to terminate contracts if laboratory performance is not acceptable. Although not related to performance, the directors of seven laboratories and centers have changed in recent years, illustrating the flexibility of the personnel system.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

NBS:

As a matter of mission, and in compliance with legislation of 1901 responsive to Alexander Graham Bell's proposal, the NBS makes its laboratory facilities readily accessible. About 750 guests are currently acquiring "hands-on" experience in NBS facilities under various formal programs. NBS brochures describe about 100 special technical facilities

and several hundred research topics to attract researchers. NBS facilities are generally designed to provide space for guest investigators. Examples follow.

The Experimental Nuclear Reactor has 25 ports providing 125,000 instrument-hours per year to more than 50 guest groups for research involving neutron scattering, measurement standards, dosimetry, trace analysis, isotope production, and radiation.

The Synchrotron Ultraviolet Radiation Facility (SURF) provides 280 MeV highly collimated, nearly polarized radiation of calculable intensity in 6 beams.

The Linear Accelerator (LINAC) accelerates electrons to energies between 1 and 10 MeV in a beam directed to either of two heavily shielded underground target rooms or to an above-ground target room where secondary neutron beams are produced for time-of-flight meausurements across distances up to 200 meters.

NBS has a variety of arrangements for joint research with universities. At the Joint Institute for Laboratory Astrophysics (JILA) in Boulder, for example, 13 NBS staff members join with 11 faculty members of the University of Colorado to conduct research involving precision measurement in physics, chemistry, and astro-geophysics. One hundred and forty three additional invited scientists and students join in the research on a revolving basis. NBS facilities are continually being upgraded and new arrangements made for joint research with institutions of learning.

NOAA:

NOAA provides access to its Federal laboratories through a variety of mechanisms: cooperative institutes with state and local universities, reimbursable programs, Intergovernmental Personnel Act (IPA), postdoctoral program, visiting scientists, and direct access to special facilities. Cooperative institutes between NOAA and universities have been established in Hawaii (JIMAR—Joint Institute for Marine and Atmospheric Research), Washington (JISAO-Joint Institute for Study of the Atmosphere and Ocean), Colorado (CIRES—Cooperative Institute for Research in Environmental Sciences and CIRA—Cooperative Institute for Research in the Atmosphere), Oklahoma (CIMMS—Cooperative Institute for Mesoscale Meteorological Services), and Florida (CIMAS—Cooperative Institute for Marine and Atmospheric Studies); and a cooperative program has been established in New Jersey. On the average, NOAA has around a dozen IPA's that range from 1-year to 4-year assignments, but the number varies from year to year. Guest worker arrangements are made between the individuals and the NOAA laboratories, but on the average about 50 guest workers per year work in the laboratories. Arrangements for direct access to laboratory facilities are usually made directly by the laboratory and the user; these are not long-term arrangements. Examples of direct access to special laboratory facilities include the Boulder Atmospheric Observatory studies, the Coastal Ocean Dynamics Applications Radar (CODAR) Program, and the Hurricane Program.

Direct access to laboratory facilities is demonstrated by a wide variety of examples. NOAA aircraft and ships are available for researchers and

investigators from external agencies and groups. Flights and cruises are often composed of NOAA researchers augmented by university, other agency, and private sector scientists. These field programs are planned through proposal submissions from various researchers, one year in advance. Once preliminary agreement has been achieved and a set of field programs has been scheduled, additional pieces of research are added to each of the field programs to fully utilize the capacity of the ships or aircrafts. For example, in fiscal year 1983 the Arctic Gas and Aerosol Program grew into a research program composed of scientists from 3 Federal agencies, 10 universities, 2 Federally sponsored private laboratories, Canada, and Norway. The program consisted of research on air pollution sources and content of the "arctic haze," on the development of polar lows over the North Atlantic, on the stratospheric-tropospheric exchange of particles from El Chichon, and on the extent and movement of ice in the polar region. In addition to these moving platforms, NOAA has fixed laboratory facilities that are accessible to universities, industry, and users of research—the Boulder Atmospheric Observatory (BAO), the National Severe Storms Laboratory's radar and lightning net, the Program for Regional Observing and Forecasting Services, the Space Environment Service Center, and the NOAA Undersea Research Program (NURP) are examples. Each of these facilities is available for cooperative programs, can provide direct services, and is accessible to outside users.

Recommendation 5-2: R&D Interactions Between Federal Laboratories and Industry

---

Department of Commerce (Productivity, Technology, and Innovation)

As the agency with lead responsibilities for Federal patent policy and the Stevenson-Wydler Technology Innovation Act, the Department of Commerce has been working to develop several government-wide policies that are consistent with the Packard Report recommendations.

The Department helped draft legislation allowing nearly all government R&D contractors to own inventions that result from Federal funding. This would automatically transfer ownership of technology developed by contract operators of government-owned laboratories to the contractors. Experience with universities shows that contractor ownership is a particularly effective form of technology transfer and leads to closer interaction with industry.

In addition, the Department has proposed legislation that would allow agencies to protect their procurement interests in Federally developed technology through use of a "Statutory Invention Disclosure." With this technique available for defensive use, agencies would only file for conventional patents on inventions—mostly from laboratories—that have commercial potential. This would reduce the government patent portfolio to the relatively few inventions most likely to be useful to industry. Again, the university experience shows that concentrating on valuable inventions leads to many forms of industry cooperation.

The Department also is developing a plan for managing Federal technology, particularly that developed in the laboratories. Key elements of the plan include incentives for closer cooperation with industry and provisions for laboratory inventors to assist in commercialization efforts.

Further, the Department has fostered use of Research and Development Limited Partnerships by the private sector to fund major technological advances. It is hoped that the facilities and staff of Federal laboratories may be involved in significant partnership developments.

The Department, through its Center for Utilization of Federal Technology, is providing several important aids to help industry identify useful Federal laboratory expertise.

NBS:

As the U.S. Central Reference Laboratory, NBS collaborates with U.S. industry in developing the measurement services needed to create, make, and sell competitive products and services. The NBS Statutory Visiting Committee, composed of five leaders of U.S. science and technology, is assisted by more than 200 leading industrial and university scientists and engineers in overseeing NBS plans, programs, and services.

NBS is currently improving its traditionally strong links to industry. For example, NBS joined with the Industrial Research Institute (IRI, whose members carry out 85% of U.S. industrial R&D) and the Commercial Development Association (whose members commercialize most of the U.S. R&D) in a survey to determine the extent of their interest in Federal R&D, how they acquire knowledge of such R&D, and how they would like to be kept informed of it—particularly the R&D carried out at NBS.

NBS recently assessed industrial interest in NBS research and development and found 219 relevant projects. These projects were test-marketed among industrial firms; NBS top executives also increased their presentations to various industrial groups. NBS developed a "How-To Primer" for Federal laboratory technology transfer and a "Federal Laboratory Directory" under the auspices of the Federal Laboratory Consortium. NBS arranged and participated in workshops in which Federal laboratories and industrial firms presented discussions of emerging technological developments. NBS has placed emphasis on the development of measurement services for high-performance semiconductor electronics, flexible automatic manufacturing, chemical engineering, materials processing, and biotechnology. Quality-control training seminars are being held throughout the United States in important industrial-process areas sensitive to measurements. Examples of external interactions not previously mentioned are:

NBS provides technical advice to 1,497 national and international standards committees and answers 5,000 inquiries about national and international product standards and practices each year.

40,000 certified samples of materials are supplied to 10,000 clients yearly.

7,000 instruments are calibrated each year.

2,000 energy-related inventions are evaluated yearly and inventions expositions are hosted throughout the Nation.

280 construction-material test laboratories are evaluated each year.

NBS has formal cooperative R&D programs with 16 industrial firms and 24 trade associations.

NBS has received approval to make its facilities available to private sector users on a controlled basis for conduct of research of a proprietary nature.

NOAA:

NOAA provides access to its Federal laboratories by industry through several mechanisms: the Office of Research and Technology Application (ORTA), guest workers (described in recommendation 5-1), laboratory outreach programs, and cooperative programs.

The ORTA, established in compliance with section 11 of the Stevenson-Wydler Technology Innovation Act of 1980, has appointed contacts in each of NOAA's laboratories. The ORTA serves as a focal point for the collection and distribution of information products about technologies developed in NOAA laboratories. In cooperation with laboratory personnel, Technology Briefs are written and distributed through a growing network of technology transfer organizations. These include the DOC Center for the Utilization of Federal Technology, the Federal Laboratory Consortium, the Sea Grant Marine Advisory Service, NOAA extension services, the non-Federal Technology Transfer Society, and state organizations such as the Ohio Technology Transfer Organization (OTTO).

Laboratory outreach programs include individual laboratory efforts to move their technology or products to the marketplace. Specific examples are the Coastal Ocean Dynamics Applications Radar (CODAR), the Doppler radar and lightning data, the NOAA Undersea Research Program (NURP), the Hurricane Program, and the data from the Geophysical Monitoring for Climatic Change (GMCC) Program. CODAR is a high-frequency radar technique developed in NOAA's Wave Propagation Laboratory to measure wave and current information from coastal sites. This technology was made available to industry, and at least one company was formed to manufacture and use this system.

The fishing industry is directly involved with the NMFS specialized facilities for new product development, product storage and handling, product quality and safety, and fishing gear development. Through these specialized research facilities the NMFS has cooperative agreements, exchange of personnel, and exchange and sharing of equipment with industry.

NOAA has attempted to expand the interaction between the laboratories and industry where appropriate. New technology for remote sensing in the atmosphere and the oceans is being developed in the research laboratories. Passive and active sensors to measure wind, temperature, humidity, and total water content are being developed. Industry, through joint programs, will be called on to develop operational prototypes for these devices. New techniques for gathering and displaying various data sets and combinations of data sets are being developed. Industry, again through joint programs, will be called upon to move these concepts into prototype systems for evaluation by NOAA service organizations.

The Geophysical Monitoring for Climatic Change Program maintains a long-term record of various atmospheric constituents that are considered a measure of the "health" of our atmosphere (e.g., carbon dioxide and ozone). These data are made available, on a regular basis, to industry and other users.

Recommendation 5-3: Simplification of Federal Procurement Procedures

The Department of Commerce has been working to extend the right of invention ownership to all classes of R&D contractors. Experience with universities shows that contractor ownership simplifies R&D procurement procedures and is a particularly effective form of technology transfer. The Department drafted and coordinated the President's February 18, 1983, Memorandum that established contractor ownership as the Administration's policy. The Department assisted in re-writing the patent section of the new government-wide Federal Acquisition Regulation (FAR) to make it conform with statutes and the Presidential Memorandum. The Department has also assisted in drafting new patent-ownership legislation.

DEPARTMENT OF DEFENSE

MISSION

Recommendation 1-1: Mission Review

The missions of Department of Defense (DOD) laboratories clearly define their role as that of performing basic and applied research for the development of military technology and equipment. These are recognized by the Packard Report as appropriate roles for Federal laboratories and are two of the major functions listed in a DOD study of required in-house capabilities for research, development, test, and evaluation (RDT&E).

Following a recent review of its laboratory organization study, the Air Force has reorganized its laboratories, placing them in product divisions to promote closer ties between the research community and the research users. The Navy completed a study in 1983 of the mission statements of the 13 laboratories that account for over 95% of the Navy's laboratory work force. The Army Materiel Development and Readiness Command (DARCOM) initiated a comprehensive review of its 20 laboratories, including their roles and missions. These laboratories account for approximately 75% of the funds that go to Army laboratories. The review is expected to be completed in 1 year.

Recommendation 1-2: Size of Laboratory

DOD laboratories are sized to accomplish their mission. Whereas doing good science may justify an increase in size of a university science department, DOD cannot justify changing the size of a laboratory based on the quality of its work alone. The quality of work is extremely important and is assessed by management and sponsors at various levels. Improving quality is always a goal.

DOD will continue to review the roles and missions of its laboratories using the results of its "Required In-House Capabilities" study as a guideline. Laboratories will continue to be sized based on mission requirements. Quality of work will be continuously reviewed by management, sponsors, and the external advisory groups being set up in response to recommendation 4-1.

FUNDING

Recommendation 3-1: Multiyear Funding

ARMY:

RDT&E funds are appropriated on an annual basis. Civilian pay raises are paid out of the RDT&E budget; there are no separate appropriations to cover such raises.

There is no evidence that a 2-year budget would provide stability to technology base funding. Supplemental RDT&E funds are needed to cover civilian pay raises to minimize turbulence in R&D mission areas.

The Office of the Secretary of Defense (OSD) must submit a pay supplemental that includes RDT&E appropriations to cover civilian pay raises for all Services. The Office of Management and Budget (OMB) should approve and forward these requests for Congressional action.

NAVY:

Funds are appropriated on an annual basis.

The Navy supports across the board R&D funding on a multiyear basis.

OSD/OMB/Congress must approve and implement multiyear appropriations.

AIR FORCE:

Funds are appropriated on an annual basis The Air Force currently funds civilian pay raises out of non-technical resources.

The Air Force does not consider instability to be a problem. It can support basic and applied research multiyear funding but prefers to deal on a year-to-year basis for big projects. The Air Force would be pleased if Congress appropriated funds to cover the pay raise.

Congressional action is required to effect a pay-raise appropriation.

Recommendation 3-2: Discretionary Funds

ARMY:

Discretionary funds constitute 10% of the Army's basic research programs; no such funds are available in the applied research program. Laboratory directors report annually, reviewing program progress, to support future funding. Laboratory directors have unrestricted use of these funds. However, in-house research is strongly encouraged. As a result, approximately 20% of these funds are used for contractual effort; 80% are used for in-house research.

No change in funding is necessary to meet the recommendation.

NAVY:

Discretionary funds have been available to Navy research activities under basic research since the mid-1950s. Applied research discretionary funding was started in the mid 1960s. The laboratory directors are given wide latitude in the use of discretionary funds to enable them to perform innovative, promising work without the procedure of formal and prior approval. The laboratory director has the authority to contract out to universities and/or industries research work that supports in-house efforts. The Navy's discretionary programs are evaluated after the fact, based primarily on biennial site reviews by the Chief of Naval Research review teams. These reviews are interspersed in alternate years by laboratory presentations to other laboratory directors and a selected panel of high level Navy research officials. A recent unpublished study of the Chief of Naval Material research centers' discretionary program (fiscal year 1966-fiscal year 1981) has revealed a sharp decline in discretionary funding while

the number of scientists and engineers engaged in discretionary programs has been cut in half since fiscal year 1967 due to decreased funding.

The Navy supports the recommendation as written. This recommendation is supported to a degree by the DOD budget guidance regarding funding of discretionary programs, which states: "However, no more than 5% of a given laboratory's funding will be in the form of In-house Laboratory Independent Research and Independent Exploratory Development (discretionary) funds." The Navy laboratories' funding for discretionary programs amounts to less than 2% of total laboratory funds. An increase to 5% would be in line with laboratory directors' needs based on a recent Navy study. It has been proposed that the "annual funding" portion of the recommendation be interpreted to mean "technology base" funding. This interpretation is considered too restrictive and it is not in line with existing DOD budget guidance for the discretionary programs.

Due to the large decrease in funding for the Navy's discretionary programs, the Director of Navy Laboratories is seeking to stem the continued down-slide by trying to establish some policies that would provide growth to the discretionary programs with particular emphasis on sizable growth in applied research in the near future. The study of the Navy laboratories' discretionary programs, cited earlier, stated that laboratory funding needs for the discretionary program amount to over 4% of the laboratories' total annual funding. Currently the Navy laboratories' discretionary program amounts to less than 2% of their total funds. Therefore, the laboratory directors feel that a significant increase in discretionary program funding is required to maintain the Navy's efforts at a reasonable level to attract highly qualified scientists and engineers and to help develop and retain a sound core of in-house expertise.

The Office of Naval Research has agreed to maintain discretionary funds as a constant percentage of basic research funds (about 7%). The Office of Naval Technology has agreed to increase the percentage of discretionary funds as a part of applied research funds (from 2% to about 5%).

AIR FORCE:

The Air Force currently maintains discretionary funds in basic research equal to 7% of the basic research budget. The Office of the Assistant Secretary of the Air Force reviews the results of basic research once a year. Laboratory directors may use basic research discretionary funds both for work done in-house and through contracts with academia and industry.

The Air Force will maintain basic research discretionary funds and initiate applied research discretionary funds.

The Air Force Systems Command will initiate and administer discretionary funds for applied research.

Applied research discretionary funds equal to 0.5% of each laboratory's applied research budget will be available for use by the laboratory director in fiscal year 1985. The percentage will increase gradually to 4% of total applied research in fiscal year 1989 and thereafter. These funds will be used for unplanned opportunities and will not be available to cover

cost growths or other problems in the planned portion of the laboratory programs. Performance of discretionary funded programs will be a factor in distribution of future discretionary funds among Air Force laboratories.

Recommendation 3-3: Carry-over Funding

ARMY:

The Department of the Army has 2-year R&D obligation authority. However, because of incremental funding guidance, the Army attempts to obligate in excess of 96% of its funds in the first year and 100% in 15 months.

There are no major problems with execution of technology base programs within the time limits as related to ongoing contracts. However, with new procurement regulations, obligation goals under Continuing Resolution Authority may not be realistic. No change in funding, however, is necessary to meet the recommendation.

NAVY:

In accordance with regulations in NAVCOMPT manual, Volume 7 paragraph 074403, RDT&E,N funds are incrementally funded to government installations (Federal laboratories) during the first year of this 2-year appropriation. The planned increment may extend up to 3 months into the following fiscal year per the authority of the Assistant Secretary of the Navy (Research, Engineering and Systems). New obligations are limited to the period of October 1 of the first fiscal year to December 31 of the second fiscal year.

If an extension of Obligational Authority is needed beyond December 31, an extension may be requested of the Assistant Secretary of the Navy (Research, Engineering and Systems). The RDT&E,N annual obligation rate established by OSD is 94%. In the first year of the appropriation, technology base funds normally reach this goal within the Navy. Therefore, due to the aforementioned, few problems are encountered concerning carrying remaining technology base funds forward into the next fiscal year.

No change in funding is necessary to meet the recommendation.

AIR FORCE:

Air Force RDT&E funds are 2-year appropriations. To assure timely appropriation and distribution of funds, the general objective is to obligate and expend current fiscal year funds for work to be done in the current year. Specific OSD goals are 94% for obligation and 61% for expenditure by the end of the first year. Contracts are incrementally funded, i.e., work done in second and subsequent years is paid for with funds appropriated in those years. However, laboratory directors have authority to obligate and expend funds in the second year of an appropriation for programs that have been delayed. After December 31 , Headquarters Air Force Systems Command determines the status of laboratory funds that have not been committed to procurement, and may reallocate funds between laboratories to assure that the funds are appropriately obligated by the end of the second year.

MANAGEMENT

Recommendation 4-1: Oversight Function

Implementation of this recommendation is in process at DOD. The Services were requested to form external advisory groups for their laboratories under the aegis of their Scientific Advisory Boards and to provide plans for how these groups would operate to perform the oversight functions. For the most part, the advisory groups will be constituted under the Naval Research Advisory Committee (NRAC), the Army Science Board (ASB) and the Air Force Scientific Advisory Board (SAB). The Army Medical R&D Command already has a separate advisory board for its laboratories. The Office of the Secretary of Defense has received implementation plans from the Services.

Recommendation 4-2: Greater Reliance on Peer Review

In the case of basic research, the involvement of DOD laboratories is small—about 4% of their total funds or roughly $240 million out of $6 billion worth of RDT&E. About $60 million or 1% of the total funds are provided to laboratory directors as discretionary funds to be used for investments in scientific areas the directors deem important, or to increase laboratory expertise in selected technical areas. In this latter case, the quality of completed work is used as a factor in distributing new discretionary basic research funds.

Peer review will continue to be used to evaluate the quality of completed basic research projects. Quality is a factor but not the only factor in determining whether or not new basic research projects will be funded. Relevance to mission as well as success in transitioning research results to further development are also factors that will be considered.

Recommendation 4-3: Finite Term for Laboratory Director

Most DOD laboratory directors are military personnel. They normally serve 3-year terms. The civilian laboratory directors are members of the Senior Executive Service (SES) and already can be (and frequently are) moved to another position as management sees fit. The performance of the director and the laboratory are significant factors in such decisions.

This recommendation has been implemented to a great extent but is still reviewed periodically. A study of the Army laboratories had two specific recommendations regarding the appointment of directors. These are being reviewed by senior Army management.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

Present DOD policy is to encourage the use of its unique laboratory facilities by universities when they are not being used to perform the laboratories' missions. The manner in which these facilities can be used

by non-DOD investigators is prescribed by DOD Directive 3202.1 and DOD Instruction 7230.7. Work will be performed for private industry when a DOD laboratory possesses unique facilities not available in the private sector. (See DEPSECDEF Memo, January 21, 1972.)

Extensive efforts are under way to facilitate DOD-university-industry interactions in both research and education. Over the past 4 years, more than 2,000 high-school students have had summer research experiences/apprenticeships in DOD laboratories or with university research under contract to DOD. In the summer of 1984, DOD will test a new program, modeled after the DOD High School Apprenticeship Program, to enable high-school science and mathematics teachers to have summer research experiences in DOD laboratories to enhance their teaching skills.

DOD has established a formal advisory body, the DOD-University Forum, which discusses issues of mutual interest to DOD and academia. One of the Forum's working groups recently completed a major report on engineering and science education. The report examined DOD's needs for trained technical personnel and made recommendations of importance to scientific and engineering personnel employed in DOD laboratories. At the undergraduate and graduate levels, DOD laboratories employ approximately 800 co-op students a year. DOD is currently examining the feasibility of providing scholarship support to co-op students. DOD's basic research programs support approximately 4,000 graduate assistants each year. In addition, each Service has established graduate fellowship or assistantship programs which this year will support almost 200 students pursuing advanced degrees in disciplines important to the defense mission. Many of these students also have summer DOD laboratory research experiences.

DOD also sponsors summer faculty research opportunities in DOD laboratories for university researchers. In 1983 more than 300 faculty members as well as some 50 graduate students conducted summer research in DOD laboratories. Participants in Air Force programs are also eligible to apply for mini-grants to continue DOD-related work during the school year.

The DOD University Research Instrumentation program will help universities buy $150 million in research equipment by fiscal year 1987. DOD, together with several major corporations, is also supporting the new National Technological University, a consortium of 24 major engineering schools, which will deliver advanced engineering degree coursework via satellite to industrial and DOD laboratories by 1985. DOD will continue to encourage use of its facilities by universities and will continue to strengthen its interactions with education at all levels.

Recommendation 5-2: R&D Interaction between Federal Laboratories and Industry

---

R&D interactions between DOD laboratories and industry are commonplace. Industry supplies the Nation's weapons and works with DOD labo-

57-279 O - 87 - 58

ratories as a matter of course in producing the means for our defense. This buyer-seller relationship with industry makes industry funding of DOD laboratories inappropriate, because DOD laboratories must evaluate the seller's products. Industry funding in DOD laboratories would create a potential conflict of interest, and the appearance of a conflict would always be present.

There are now several DOD activities aimed at improving interactions and information exchange between DOD and private industry. Information liaison offices have been set up by the Services nationwide to provide information on DOD operations and interests to DOD contractors. In response to the Stevenson-Wydler Act, every DOD laboratory now has an Office of Research and Technology Application (ORTA). The ORTA is a point of contact which provides information on the laboratory's technical activities to those outside of DOD and is responsible for assisting in technology transfer to state and local governments and to private industry. DOD representatives also interact closely with industry researchers in reviewing industry's Independent Research and Development (IR&D) Program. Through the Defense Technical Information Center and DOD's Information Analysis Centers, DOD research results are made available to DOD's present and potential contractors.

The Small Business Innovative Research Act requires that a percentage of all DOD research funds be set aside for this highly innovative segment of private industry. Funding decisions on small-business research proposals are made at the project-manager level, thus encouraging additional interactions.

Other examples of DOD activities promoting interactions include the tri-Service Information for Industry offices in Alexandria, Virginia, Dayton Ohio, and Pasadena, California, and the participation of both industry and university personnel on the Defense Science Board and the Scientific Advisory Boards of the Services. The latter are being given the additional role of evaluating the performance of DOD laboratories. DOD is committed to continuing its extensive interaction with private industry.

Recommendation 5-3: Simplified Federal Procurement Procedures

A permanent working group of procurement specialists has been established within the DOD Laboratory Management Task Force (LMTF) to simplify procurement procedures on a continuing basis. Another group is concentrating on simplifying the contracting procedures for the Small Business Innovation Research Program with the aim of using the procedures as a model for other procurements. In addition, a report has been prepared entitled, "Actions Required to Improve Research and Development Procurement and Contracting."

Recommendation 5-4: Support to Military Operating Forces

A task force formed by the Office of the Secretary of Defense is considering new approaches to provide closer coupling of the Service labora-

tories with the operating forces. The task force has identified a number of Service programs wherein the laboratories provide support to the operating forces.

The Army Materiel Development and Readiness Command (DARCOM) has a number of programs to identify requirements for R&D support of the operating commands. Teams of DARCOM scientists regularly conduct fact-finding missions to field units for the purpose of identifying problems in the operational use of communications equipment requiring R&D solutions. DARCOM maintains 19 detachments of on-site liaison representatives at Army training centers and schools to identify problems requiring R&D support. These needs are communicated directly to the appropriate DARCOM laboratories.

The Naval Material Command co-locates approximately 30 scientists and engineers on a rotating basis with their operational commands under the Navy Science Assistance Program. The rotational assignments provide the scientists and engineers with operational experience and improve communications with the laboratories in operational problems.

The Air Force has a variety of procedures for identifying the R&D needs of the operating commands. Formal documents to identify logistics needs, research needs, and R&D objectives are developed through cooperation among the Air Force Logistics Command, the Air Force Systems Command, and the operational commands. The Strategic Air Command hosts an annual, week-long conference with laboratory participants to identify R&D objectives and to foster informal cooperation. The Tactical Air Command has a point of contact for each development-program element and is consulted for comments on relevant exploratory and advanced development programs. The Chief Scientist of the Air Force has initiated a program whereby the chief scientists of Air Force organizations meet twice a year at locations of the operating forces. The goal of these meetings is to enhance interactions between the operating forces and the Air Force R&D community.

The laboratories' External Advisory Groups will be requested to include support of operating forces among the important criteria against which they measure the performance of the DOD laboratories.

DEPARTMENT OF ENERGY

MISSION

Recommendation 1-1: Mission Review

On July 28, 1983, as part of the institutional planning process for fiscal year 1984-fiscal year 1989, Secretary Hodel issued the Department of Energy's (DOE's) policy guidance on the role and missions of the multiprogram laboratories. The Secretary's policy guidance is based on his Congressional statement on the Federal role in energy R&D and is consistent with the National Energy Policy Plan.

On February 15, 1984, the Laboratory Management Council (LMC) developed a generic laboratory role statement and reviewed and revised all proposed laboratory mission statements with special attention to their clarity and specificity. In addition, the programs have been urged to develop 5-year program planning guidance and mission area assignments for the laboratories and to appraise laboratory program performance regularly.

Beginning in 1984, annual laboratory appraisals will be carried out by the cognizant Operations Office to evaluate overall laboratory performance in carrying out their assigned missions. The Headquarters program performance review will be part of the overall laboratory management appraisal.

Recommendation 1-2: Size of Laboratory

The institutional planning process of the Department results in review of laboratory workload consistent with missions and quality of work. The budget process determines increases or decreases in laboratory work depending on the quality of the past year's work, and any overall change in missions or directions made as a result of Administration or departmental policy. For example, recent mission redefinitions have resulted in significant decreases in laboratory size in the area of applied technologies, particularly those viewed as having near-term commercial benefits.

The multiyear program plans will provide an appropriate foundation for long-term mission area assignments to laboratories, justification for stable multiyear budget authorizations, and a sound basis for a more effective 5-year institutional planning process. Although they are limited in controlling fluctuations in budgets, the Assistant Secretaries will encourage long-term mission area commitments to laboratories and continue to give high priority to minimizing budget fluctuations. DOE's Internal Review Budget crosscuts will be used to control fluctuations in the planning stage, and ensure proposed laboratory program budgets do not fluctuate randomly without management attention.

The Laboratory Management Council, as part of its consideration of laboratory 5-Year Institutional Plans will review the proposed size of laboratories based on approved missions. As part of the Internal Review Budget procedures, the LMC also reviews proposed budgets of multi-

program laboratories to encourage stability consistent with mission needs and resources, and for consistency with mission statements, and appraisals of performance. The LMC will bring problems to the attention of the Secretary for resolution.

PERSONNEL

Recommendation 2-2: Independent Salary Administration for Government-Owned Contractor-Operated (GOCO) Laboratories

DOE laboratories are responsible for exercising management judgment and discretion in the administration of employee wage and salary programs. DOE retains only the right to approve a limited number of top level salaries and annual salary increase funds before such actions are implemented. DOE approval is based on data that the contractor itself develops as basis for its decision making purposes and that show the action to be consistent with programs in the private sector.

DOE now plans to delegate approval authority to the laboratories for salaries up to $60,000.

DOE develops internal guidance to be used in determining the reasonableness of laboratory personnel compensation costs. Such guidance was recently updated and will continue to be revised to reflect current compensation trends for employees with comparable jobs in appropriate labor markets. Experience in the private competitive economy is used as the primary standard of reasonableness with no reference to Civil Service compensation levels.

DOE will periodically review the threshold levels for individual salary approvals to ensure there is no increase in the percentage of total salary actions reviewed. DOE will also continue to refine and clarify criteria for market-basing of salary structures, so that laboratories will be able to make periodic adjustments with only minimal discussions with DOE.

FUNDING

Recommendation 3-1: Multiyear Funding

Taken literally, the recommendation does not call for funding stability but for funding *predictability*, so that staffing and research levels at laboratories can be properly planned. Much of the apparent instability in DOE laboratory funding in recent years has been a direct result of the Administration's effort to focus the laboratories on longer term programs and projects more appropriate to DOE's R&D mission, and away from near-term, more developed technologies that are properly the responsibility of the private sector.

Greater predictability of funding could be enhanced by multiyear authorization and appropriation of funding. Failing that, funding predictability could be improved by measures to better ensure the passage of annual Congressional appropriation bills prior to the end of the fiscal year.

The DOE has secured multiyear authorizations from Congress and hopes to do so again. However, the House Rules Committee and the

Senate Government Affairs Committee may recommend a 2-year authorization and appropriation cycle to the Congress, presumably as amendments to the Budget and Impoundment Control Act of 1974. If the Congress does not approve the proposed action, some improvements could be gained through greater use of multiyear program planning documents, cleared by the Office of Management and Budget and sent to Congress for comment and "approval," or inclusion of report language with the annual appropriation bills that would explain the position of the Appropriations Subcommittee regarding the future direction and funding profile of certain basic and applied research programs. Unlike multiyear appropriations, neither of these partial solutions would provide funds or have the force of law, but they would at least be expressions of Congressional intent and might provide some additional measure of predictability to the management of R&D.

Recommendation 3-2: Discretionary Funds

In a policy statement issued on December 13, 1983, Secretary Hodel clearly established policy for use of funds for exploratory development at multiprogram laboratories. Under this policy, laboratories are allocated reasonable amounts of funds, and laboratory directors exercise authority in choosing projects for funding. Laboratory work is scrutinized at an annual review of institutional planning, where the highest management level looks at both the process and the results of such funding. Those laboratories that do well in carrying out the general goals of exploratory R&D funding (e.g., spurring research vitality, generating new ideas, attracting talented scientists) receive increased funding.

Prior to the issuance of this policy statement, there were similar discretionary funded efforts, but without central and consistent guidance. The current procedure for such funding is clear and consistent with the Packard Report recommendations. The percentage of exploratory R&D funds is expected to range from about 1% to 5%.

Recommendation 3-3: Carry-over Funding

DOE appropriations for research and development are no-year funds. Therefore, no change in funding is necessary to meet the recommendation.

MANAGEMENT

Recommendation 4-1: Oversight Function

The Laboratory Management Council is reviewing ways of implementing the recommendation by utilizing existing mechanisms where effective and modifying processes where necessary. Oversight panels exist for Argonne National Laboratory (ANL) and Brookhaven National Laboratory (BNL), and one was recently included in the new Oak Ridge National Laboratory (ORNL) contract. Weapons laboratories have similar panels reporting to the University of California. Plans are being developed to

ensure that these groups can and will effectively perform the required oversight functions.

Recommendation 4-2: Greater Reliance on Peer Review

The proposal preparation and approval process within the laboratories has many elements comparable to traditional peer review, including review by advisory committees to the laboratories. Areas such as high-energy physics have extensive peer review of research results prior to and including the publication process. Furthermore, DOE carries out results-oriented peer reviews of major laboratory research programs compared to similar research in universities (e.g., the 1982 Assessment of Basic Energy Sciences Programs). Several efforts have also been made toward relying to a greater extent on peer review evaluations in funding specific energy research programs at the laboratories.

In addition, a working group of affected program offices has been established to propose guidance on how best to accomplish peer review of basic research at the laboratories. The Laboratory Management Council will review the proposed actions in 1984 and recommend any necessary changes in departmental policy in this area.

Recommendation 4-3: Finite Term for Laboratory Director

A DOE Order on uniform laboratory appraisal was issued on October 6, 1983. It requires annual, results-oriented appraisals at all the major multiprogram laboratories. The Operations Office appraisals will include laboratory director accountability, but the prime responsibility for laboratory performance will continue to remain with the contractor. Review of director's accountability when coupled with contact extend/compete decisions (which occur every 5 years) will result in a process that meets the objective. In the last 5 years, new directors have been appointed at 7 of the 9 major multiprogram laboratories.

Recommendation 4-4: Congressional Oversight of DOE

Compared to other departments, DOE has had the most changes in missions in the past 7 years evolving from the Atomic Energy Commission, to the Energy Research and Development Administration, to the Department of Energy. In a letter on July 28, 1983, Secretary Hodel issued the Department's policy guidance on the missions of DOE and its multiprogram laboratories. The Secretary's policy guidance is based on his Congressional statement on the Federal role in energy R&D and on the National Energy Policy Plan IV which was published and forwarded to Congress in October, 1983.

Recent stabilization in renewable energy programs and reductions in commercialization-related activities, coupled with the National Energy Policy Plan and the Secretary's statement on Federal and DOE labora-

tories roles, have put the Department in the best position to date to communicate and affirm DOE missions and to participate in discussions with Congress regarding DOE oversight and reduction of the number of Congressional committees with budget and oversight responsibilities for DOE programs.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

Secretary Hodel's policy guidance to the laboratories endorses the recommendation and encourages the laboratories to improve accessibility to facilities by universities and industry. The Secretary has assigned a generic role to the laboratories to provide appropriate use of the laboratories' major capital-intensive facilities to the scientific community.

The laboratories continue to be important complementary resources to university-based research and education. About 5,000 university faculty members and students participate each year, generally during the summer, in laboratory-sponsored research and training programs. The budget for the DOE University Laboratory Cooperative Program has been significantly increased in fiscal year 1985 to support additional faculty/student research appointments. Significant funding continues for operation of major user-oriented research facilities at the laboratories; for example, about 40% of the Basic Energy Sciences budget in fiscal year 1985 will support laboratory research facilities which are used by university scientists. In fiscal year 1985 the number of undergraduate students in summer programs at the DOE laboratories will double, from 600 to 1,200. In addition, the laboratory directors have been encouraged to increase support for post-doctoral research appointments and for faculty "sabbatical" year research.

A "User's Guide to DOE Facilities" was published in March 1984 to provide information about unique laboratory facilities available to industry and universities for conducting their own research on-site at the laboratories using equipment available only at DOE laboratories. There are significant examples of industry and university participation in the planning for and use of the facilities such as the Combustion Research Facility at Sandia National Laboratories (Livermore), and the National Synchrotron Light Source at Brookhaven National Laboratory. To further encourage use of DOE facilities by universities and industry, the Department has issued a class patent waiver covering data and patent rights to discovery and inventions made by users of such facilities. The response has been an increase in user interest and participation.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

DOE has implemented an R&D Technology Transfer Program responsive to the Stevenson-Wydler Act (P.L. 96-480). This program establishes DOE policy that technology-transfer activities, as required by P.L. 96-480, are legitimate functions of the R&D laboratories and will be conducted. To

meet both the spirit and the intent of P.L. 96-480, the Department has also issued guidance to the laboratories encouraging consulting by laboratory personnel. Such activity has increased as a result. Also as a result, technology-transfer activities at the laboratories have increased, and the Department, in consultation with the laboratories, has identified barriers to technology transfer and has addressed them. The Department will continue to identify barriers to technology transfer and to resolve them in the future. A senior-level working group has been established to review the Department's work-for-others policy and procedures to facilitate interactions with industry.

Secretary Hodel has assigned generic roles to the laboratories as follows: (1) to provide for and encourage the transfer of technology developed at the laboratories to the private and public sectors, and facilitate an interactive climate among the national laboratories and industry; and (2) to make special capabilities available for public and private sectors on a reimbursable basis. Personnel exchange programs between industry and laboratories, as well as industry-funded work-for-others projects, are being encouraged.

The laboratories have established a close relationship with the Industrial Research Institute (IRI) to stimulate interactions. A series of "Spotlight on a Laboratory" reports in cooperation with IRI has been initiated to encourage industry access to facilities and to communicate work of potential commercial interest. Industry reaction has been quite favorable so far. To further encourage R&D interactions, DOE has issued a class patent waiver for inventions arising from reimbursable work-for-others and for work at DOE user facilities. The response has been an increase in interactions with industry.

Recommendation 5-3: Simplifying Federal Procurement Procedures

---

Regarding university contracting procedures used in DOE, a working group has been established to recommend ways to simplify these procedures. As part of this process, DOE is converting many university awards from contracts to grants. Also, emphasis has been placed on consistent interpretation of DOE university procurement regulations and procedures by all field elements.

In the contracting area, the Operations Offices, not the GOCO laboratories, are agents for the Department. Special attention is paid to ensuring that the laboratories are not used as "pass-through" mechanisms or as a way to bypass the Federal procurement process. The laboratories do, when assigned, act as technical managers for projects, which includes appropriate subcontracting to industry and universities. Subcontracting by the laboratories in 1983-1984 was approximately $1 billion.

DEPARTMENT OF HEALTH & HUMAN SERVICES: NATIONAL INSTITUTES OF HEALTH

MISSION

Recommendation 1-1: Mission Review

The mission of the National Institutes of Health (NIH) is to improve the health of the Nation by increasing the understanding of processes underlying human health, disability, and disease; by advancing knowledge concerning the health effects of interactions between man and the environment; and by developing and improving methods of preventing, detecting, diagnosing, and treating disease.

NIH accomplishes this mission through: support of biomedical research in universities, hospitals, and research institutions in this country and abroad; conduct of biomedical research in its own laboratories and clinics; support of training for promising young researchers; development and maintenance of research resources; identification of research advances that have significant potential for clinical application, and the facilitation of the transfer of such advances to the health care system; and promotion of effective ways to communicate biomedical information to scientists, health practitioners, and the public.

New organizational or administrative entities have been established in response to changing aspects of the NIH mission; notable examples are the Office for Medical Applications of Research (OMAR) in 1977, and the National Toxicology Program (NTP) in 1978.

The Director of NIH, utilizes the Advisory Committee to the Director as a high-level outside consultative body to discuss management issues. Currently, the elements encompassed in pursuit of the primary NIH mission are being examined by a committee of the Institute of Medicine of the National Academy of Sciences, which is conducting a "Study of the Organizational Structure of the National Institutes of Health." Three panels are addressing the following aspects: historical issues, current organization, and alternatives. The Alternatives Panel's considerations include (1) "scientific opportunity" and "burden of illness" as criteria for setting research priorities, (2) the balance between basic and targeted research, (3) the balance between intramural and extramural research, (4) the balance between funding mechanisms such as grants and contracts, and (5) how to promote and stimulate priority or neglected research areas.

Recommendation 1-2: Size of Laboratory

The NIH is composed organizationally of 11 different institutes and several research divisions. These components support research extramurally through grants and contracts to outside organizations, principally universities. Most also conduct an in-house research program, called intramural research. The latter accounts for 13 percent of the R&D budget.

The emphasis, intramurally, is in basic research, which has possibilities of ultimate payoffs far in the future (e.g., advances made possible by the recombinant DNA biotechnology revolution), and on research better adapted to an in-house type of operation (e.g., long-term research on slow viruses and follow-up of an aging population over a lifetime). Such basic research is essentially limited by the magnitude of resources available.

A variety of indicators of quality of research effort all point to the premier status of the intramural program. There is the recognition by outside awarding bodies (4 Nobel Prizes, numerous Lasker Awards, etc.), the highly favorable citation and publication analysis, and the disproportionately large number of academic and investigative leaders throughout this Nation and the world who received research training at NIH (NIH "graduates").

While it is regarded that the intramural program has achieved a reasonable size for the present, there will from time to time be limited expansion dictated by external factors, such as the proposed new Arthritis Institute. In cases of significant resource additions, most program expansion will, of necessity, occur in the extramural area, owing to space or full-time-equivalent position constraints.

The NIH agrees that the size of its laboratory operation should be appropriate to its missions and the quality of its research. As new health demands and new scientific opportunities develop, the NIH will do its best to mobilize the resources for expanded intramural and extramural programs. Growth, if and when it takes place, should be gradual enough to be sustained.

FUNDING

Recommendation 3-1: Multiyear Funding

NIH funds are appropriated on an annual basis. With regard to pay raises, the Congress may appropriate supplemental funds for all or part of the pay raise, may approve a transfer from another appropriation, or may provide no dollars and require NIH to absorb the cost.

NIH supports a 2-year appropriation for both in-house and extramural research, and is in favor of a pay raise appropriation.

Two-year appropriation would require modification to the appropriation language for each NIH account and approval by Congress. The Office of Management and Budget (OMB) and Congress must approve pay raise appropriation.

Recommendation 3-2: Discretionary Funds

The NIH intramural research program is executed under the discretion of the director and scientific director of each of its institutes in accordance with the broad program goals and objectives of the Administration and Congress, and thus is considered to be 100% discretionary.

No change in funding is necessary to meet the recommendation.

Recommendation 3-3: Carry-over Funding

NIH has 1-year obligation authority; no carry-over authority.

NIH recommends that 1% of total appropriations be permitted to be carried over for 90 days.

Appropriation language for each NIH account would require modification and approval by Congress.

MANAGEMENT

Recommendation 4-1: Oversight Function

Excellence of a laboratory is determined largely by the quality of an individual scientist's research. The determination of quality includes the evaluation of original publications in the scientific literature (their impact on an area of science can be assessed in a quantitative way by citation analysis) and the recognition accorded a scientist by peer groups (evidenced by election to prestigious societies, receipt of prizes or awards, or other measures of "standing" in a scientific field). An intramural scientist's research is reviewed (1) by external Boards of Scientific Counselors at least every 4 years, (2) by the NIH Board of Scientific Directors at a time when the scientist is considered for tenure or promotion, and (3) by the laboratory and branch chiefs on an annual basis. The first two of these processes, as described below, represent external reviews with respect to each component Federal laboratory.

Recommendation 4-2: Greater Reliance on Peer Review

The NIH intramural research programs are, in a very real sense, critically reviewed by peers from outside the Federal Government, on a fixed schedule, with important implications for the size and direction of the programs and for the funding and other support for individual laboratories and scientists. (See comments on previous recommendations.) Each institute has its Board of Scientific Counselors for this review purpose.

NIH does not view the "competitive peer review process" as the proper mechanism for dealing with in-house staff. An ongoing process of review and evaluation is more appropriate to an operation in which one's own employees are engaged in research, as contrasted with extramurally supported grantee or contractor projects.

Recommendation 4-3: Finite Term for Laboratory Director

Within the framework of the NIH Intramural Programs, this management consideration related to the scientific directors, and to the laboratory and branch chiefs. The specific projects within each laboratory and branch are reviewed at least every 4 years by the outside Boards of Scientific Counselors and annually by the scientific director.

A scientific director of an NIH institute or division is jointly accountable to the institute director and to the NIH Deputy Director for Intramural Research regarding quality, productivity and program relevance. On several

occasions in the past, a scientific director has been replaced because of inadequacies in performance. Similarly, laboratory or branch chiefs are accountable to scientific directors and may be replaced as necessary.

A proposed new pay and personnel system for NIH scientists (pertinent to Recommendation 2-1 of the Packard Report) has been developed, first, by the Committee on Pay and Personnel Systems in Intramural Research and, second, by the NIH Committee on Pay of Scientists. These two committees recommended consideration of renewable (e.g., 5-year) terms for laboratory/branch chiefs (after age 70, renewable annually).

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

By far the largest part of the NIH budget is devoted to support for extramural research performed principally at universities. In 1985, research project grants initiated by investigators amounted to $2.7 billion.

The academic community is provided access to NIH intramural laboratories and clinics through Guest Researcher appointments and via a number of temporary-type personnel mechanisms, such as Experts, Intergovernmental Personnel Act appointees, summer employment, etc. The NIH will continue to provide the opportunity for academic researchers to take advantage of the unique facilities, equipment, or expertise of the NIH intramural laboratories and clinics.

NIH has no policy that would preclude an industry employee from participating at NIH under a Guest Researcher appointment, provided that a determination was made that no conflict of interest existed and that planned research was consonant with the goals of the host laboratory. However, the relatively small number of industry scientists who have been Guest Researchers may be due to concerns that their proprietary interests would be jeopardized by signing the Guest Researcher Agreement. This document requires adherence to Executive Order 10096 with regard to any inventions conceived or actually reduced to practice in performance of the scientists' work at NIH. In fact, however, recent changes in Federal patent policy make cooperative ventures between the public and private sectors more attractive. A Committee on Joint NIH-Private Sector Endeavors, chaired by the Deputy Director of NIH, has formulated a set of general principles for participation in joint projects. An "inventory" of such projects will be maintained for reporting and monitoring purposes.

The Foundation for Advanced Education in the Sciences (FAES) at NIH is a private institution chartered in the State of Maryland. In collaboration with the Johns Hopkins University, a formal Ph.D. curriculum has been established wherein the students take their course work at Johns Hopkins and do their thesis research at NIH, under an NIH intramural scientist preceptor.

Through its extramural research and training programs, the NIH supported over 5,000 post-doctoral trainees in fiscal year 1983. Some of these individuals will select the intramural NIH laboratories and clinics as the location for their training. In addition, the staff fellow program brings many junior-level scientists to NIH for temporary appointments ranging from 2 to 7 years. A small fraction will ultimately be offered a permanent

position at NIH; the majority will assume positions in the private sector, typically in academia, but now increasingly also in the biotechnology industry.

The NIH Scientific Faculty, suggested as the new personnel system for scientists at NIH, proposes to use the TIAA-CREF retirement system which is in use at most universities. Availability of this option would create more opportunities for mobility between NIH and the academic sector (perhaps several times during a career).

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

---

Technology transfer at NIH was given formal recognition in 1977 with establishment of the Consensus Development Program. The Office for Medical Applications of Research was created in the Office of the Director to serve as its administrative focal point.

The Consensus Development Program has three primary objectives: (1) to provide a setting for the evaluation and review of the scientific soundness of a health or health-related technology, with emphasis on safety and efficacy; (2) to aid in the diffusion of knowledge of advances in biomedical technology through dissemination of the findings from the consensus development process to physicians and the consumers; and (3) to facilitate the diffusion, adoption, and appropriate use of those technologies found to be sound.

To date, nearly 50 statements on topics ranging from the treatment of breast cancer to the removal of third molars have been distributed. Consensus statements are produced by persons outside the Federal Government and are designed to serve as guidelines for the physician and the patient. The emphasis is placed on scientific evaluation, but social and economic considerations can have an impact in the assessment of a given technology. As a result of consensus development evaluations, it is hoped that the use of those technologies found to be scientifically sound will increase, and that the use of those that receive no such endorsement will diminish, thus improving the quality of health care.

The Committee on Joint NIH-Private Sector Endeavors has articulated general principles to guide the establishment and conduct of joint activities with commercial organizations. Issues to be considered include (1) the programmatic importance of the project to NIH, (2) the reasons for pursuing partial or total outside support, (3) the scientific integrity of a jointly sponsored research project (e.g., data management, quality control, decisions to modify protocol, release of study results), (4) the integrity of NIH (e.g., implied endorsements, advertisements), (5) the accuracy of scientific information to be disseminated, and (6) legal and policy issues (e.g., patents, gifts, solicitation of contributions, conflicts of interest, peer review).

A number of patented inventions made in NIH laboratories have been licensed to industry. Most licenses (some 54, through July 1983) awarded were non-exclusive, although 10 exclusive licenses were also granted during this period. Inventions include newer biotechnology advances (e.g.,

monoclonal antibodies against various viruses), analytical techniques (e.g., fiber-optic pH, oxygen and carbon-dioxide sensors, countercurrent extraction and chromatography instruments), and therapeutic modalities (e.g., anti-cancer agents). A recent formal agreement between Damon Biotech, Inc. and the National Cancer Institute (NCI) illustrates the kind of mutually advantageous arrangement that can be worked out between government and industry. In the latter case, Damon possessed proprietary knowledge of certain encapsulation technology, including biological materials and living cells within semi-permeable membranes. The NCI wished to explore the possible advantage of such technology in cancer research.

DEPARTMENT OF THE INTERIOR: U.S. GEOLOGICAL SURVEY BUREAU OF MINES

MISSION

Recommendation 1-1: Mission Review

USGS:

The Director of the U.S. Geological Survey (USGS) has indicated that laboratory research will support USGS missions. Program reviews and evaluations have been the major method of determining laboratory objectives.

The present planning and budget formulation process will continue to be the method by which laboratory mission and program mission are linked. During the planning process, new programs and new initiatives to expand are proposed. These are reviewed at the division and directorate levels in terms of their authority in supporting the missions of the USGS as defined by the Organic Act and subsequent legislation. These initiatives when proposed in the budget process are reviewed by the Department of the Interior, the Office of Management and Budget (OMB), and Congress in terms of their contribution to USGS mission objectives.

BOM:

Each of the four mining research centers in the Bureau of Mines (BOM) has been designated as the lead center for certain mining research areas. Mission statements defining the role of the mining research centers have been prepared. The mission of each of the six minerals and materials research centers has regularly been examined to assess the need for redefinition in keeping with the overall mission and goals of the Bureau.

The Bureau of Mines makes the special capabilities and expertise of the laboratories available to others, consistent with current policy and regulations.

Recommendation 1-2: Size of Laboratory

USGS:

USGS has relied specifically on the planning/budget formulation process to determine the size of its laboratories.

USGS has found that the current planning/budget formulation process is a very effective means of determining optimal laboratory size. USGS will continue to use this process. Although the total budget will have a significant impact on the size of laboratories, other factors relating to mission and other agency requirements will be influential.

BOM:

The scope of Bureau research depends upon national priorities. Thus, the size of Bureau research centers has changed with changing scope.

For example, as the role of Federal research evolved from developmental to more basic research, the pilot plant facility at Boulder City, Nevada, was closed in fiscal year 1983. In an earlier example, when the goals of a cooperative experimental ironmaking blast furnace were reached, the steel industry and the Bureau concurred in closing the facility.

FUNDING

Recommendation 3-1: Multiyear Funding

USGS:

Funds are appropriated on an annual basis, with no separate appropriation for research.

USGS supports R&D funding on a 2-year basis if that funding is predictable. The appropriation would have to allow for increases for pay raises, cost-of-living allowances, and supplementals for unforeseen circumstances of a significant nature.

No agency action is required until the Executive Branch (represented by the President's Science Advisor and the Office of Management and Budget) and the Congress jointly agree to the funding recommendation.

BOM:

As an agency of the Administration, the Bureau must conform to Administration policies and is unable to anticipate Congressional actions. Therefore, plans for the affected programs have been made only after Congressional intent is clear. This has resulted in delays in program implementation and in obligating the added funding.

Recommendation 3-2: Discretionary Funds

USGS:

USGS basic earth science research is conducted within the broad program goals and objectives of the Administration and Congress and is considered to be completely discretionary. Research projects and publication of results are reviewed through a process of peer review and executive approval which maintains the highest scientific standards.

No change in funding is necessary to meet the recommendation.

BOM:

Pioneering research has been an established practice. For the last 30 years the BOM has authorized the use of up to 10% of its R&D funds for this research in-house. The efforts are periodically reviewed by research center management and the more promising efforts become formal research projects after review and approval by Headquarters management. Funding of cooperative research programs with universities and industries is constrained by Federal procurement regulations.

57-279 O - 87 - 59

Recommendation 3-3: Carry-over Funding

USGS:

USGS has 1-year obligation authority; no carry-over authority.

The USGS recommends that 1% of total appropriations be permitted to be carried over for 90 days.

Appropriation language for the USGS account, including research funded by reimbursement, requires modification and approval by OMB and Congress. As part of the 1986 budget process, the USGS will seek carry-over authority from Congress through appropriate Department of the Interior channels to OMB.

The 1986 USGS preliminary budget to the Department of the Interior will contain a request for carry-over authority.

BOM:

The Bureau of Mines follows OMB guidance.

MANAGEMENT

Recommendation 4-1: Oversight Function

USGS:

Ongoing internal program evaluations include laboratories. USGS scientists frequently coordinate research efforts with universities and other governmental units. Periodic meetings with state geologists provide considerable input to the USGS regarding relevance of research efforts to public needs. Other formally established advisory groups make recommendations to USGS, which, in turn, affect research at the laboratory level. These are the advisory groups established to implement USGS delegated coordination responsibilities under OMB Circular A-16, (coordination of National and state mapping requirements), and A-67 (coordination of Federal and non-Federal water data and analysis activities). Specifically for geological programs, there is a committee advisory to the USGS under the aegis of the Board on Earth Sciences of the *National Academy of Sciences/National Research Council* (NAS/NRC).

USGS is continuously examining ways to increase the effectiveness of its laboratories. There will be a continued effort to make use of advisory and peer groups that represent educational, industrial, and other government sectors.

BOM:

The performance of the research centers is evaluated by the two assistant directors responsible for research. Technical personnel from the Mine Safety and Health Administration periodically review and evaluate the Bureau's Mine Health and Safety Research Program. There have also been several reviews of important parts of the Bureau's research program by committees of the National Academy of Sciences with strong industry and university representation. Any tendency toward micromanagement has been decreased by cutting in half the size of the Headquarters research management staff during the past 2 years. Changes have

been made in the procedures for review of on-going mining research projects which also should help prevent micromanagement of the research centers by Headquarters staff.

Recommendation 4-2: Greater Reliance on Peer Review

USGS:

As part of the annual program/budget development process, the USGS laboratories outputs and accomplishments are peer reviewed. Each research project is reviewed at the first level of supervision several times per year to assure that the project is accomplishing its objectives. Ad-hoc committees are appointed at higher levels as necessary to review specific programs. The many publications that are published in external journals receive extensive peer review by scientists from other research sectors.

The USGS plans to continue its present review practices. They have been found to be effective in ensuring products of a high quality and a high level of productivity that reflect the missions of the survey.

BOM:

There is competitive review of all proposals for contract research. Proposals for new in-house research projects are evaluated and prioritized by committees of technical peers from the research centers and Headquarters staff. Technical personnel from the Mine Safety and Health Administration provide half the members of the committees that evaluate proposals or in-house research on mine health and safety.

Recommendation 4-3: Finite Term for Laboratory Director

USGS:

The Director of the U.S. Geological Survey is a political appointee and serves at the pleasure of the President. Appointment of directors since the establishment of the USGS in 1879 has been done in consultation with the National Academy of Sciences. The procedure of recent years has been for NAS, at the request of the Secretary of the Interior, to organize a nominating committee of leading earth scientists. The committee prepares a list of nominees in priority order from which the Secretary makes his selection.

BOM:

BOM research centers directors are at GM-15 and Senior Executive Service (SES) levels. They are responsible to an assistant director at Headquarters and are subject to individual performance plan standards. During the past decade, several research center directors have been placed in less critical positions when their performance was judged less than fully satisfactory by higher Bureau management.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

USGS:

Throughout its more than 100-year history, the USGS has encouraged close interactions with universities and industry through mutual research and sharing of laboratory facilities. A NAS/NRC committee consisting of people from industry and academia exists partly to facilitate such interactions. The USGS will continue to implement new recommendations from this committee. Cooperative projects will continue to be looked at on a case-by-case basis.

The USGS will continue to make the special capabilities and expertise of the laboratories available to others, consistent with current policy and regulations in this area. Examples of USGS facilities used by university personnel include the TRIGA reactor, electron microprobes, transmission electron microscopy, and mass spectrometers. Research in mineral and energy resources with industry is rather inhibited because of proprietary problems. An exception is the USGS Core Library in Denver which stores samples of cores from wells drilled principally in the western and central United States. Approximately 400 visitors from industry use the facility each year.

In addition to more formal arrangements with the academic community listed below, the USGS and academic scientists carry on a continuous dialogue through the usual channels. Many joint publications are written, involving no transfer of funds. The USGS employs about 150 university professors on a when-actually-employed basis and is thus able to utilize the talents of some of the more gifted academic researchers for its mission.

The USGS has traditionally played a strong role in education in the geological sciences. Examples are:

About 10 National Research Council postdoctoral fellows are in residence at any given time.

The USGS employs from 50 to 75 undergraduates as field assistants each summer, through a formal arrangement with the National Association of Geology Teachers. Four hundred students compete for the positions each year; graduates of the programs are especially desirable to oil companies, who allocate extra points to them in their rating system.

Two hundred other summer jobs are given to students each year under regular summer-employment programs. Many of these positions also are field assistantships.

Graduate internships are given to some 30 M.S. and Ph.D. students. They are funded for actual time worked, and many derive a thesis from their work. Full use of laboratory facilities is available to them. About two permanent positions per year are allocated to graduates of this group. In addition, the USGS participates in the Federal Junior Fellow Program by placing 70 talented, college bound, high school graduates who are interested in careers in governments.

A plan is being drawn up for a USGS lecture program at historically Black colleges and universities. In addition, research projects were funded at two of these institutions in fiscal year 1984.

A number of students use USGS facilities for thesis work on an ad-hoc, non-employment basis.

Over 50 USGS employees serve as Adjunct Professors around the country and teach evening courses; many more lecture at universities on invitations.

BOM:

The Bureau of Mines has always encouraged close interactions with universities and industry through mutual research and sharing of laboratory facilities. Most BOM laboratories are located close to university campuses and maintain an active association with those institutions, with joint use of laboratories. Industry personnel have historically had the use of BOM laboratories in cooperative studies.

The BOM will continue to make special capabilities and expertise of the laboratories available to others, consistent with current policy and regulations in this area. Cooperative projects will continue to be looked at on a case-by-case basis.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

---

USGS:

From its inception over a century ago, USGS has made communication and dissemination of the results of its research an integral part of its mission. The USGS spends nearly $30 million per year on what can be called technology transfer in its broadest sense.

The fiscal year 1983 Congressional budget for the first time specifically allowed the USGS "to enter into collaborative projects and to accept contributions" from outside sources. This development has greatly increased USGS capability for cooperation with industry. The USGS and the minerals, fossil-fuel, and geothermal industries have had considerable information exchange for many years. Strict guidelines have been prepared on acceptance of contributions by the USGS and on cooperative research, the most important one being that results of projects must be open to the public. The USGS continues to encourage inquiries on cooperative research without actively soliciting joint projects. Owing to the sensitive nature of its mineral and energy properties, the oil and mineral industry is more sensitive than most to the public nature of joint cooperation. The NAS/NRC committee is addressing this problem to suggest future areas of cooperation between the USGS and industry. Examples include research on fossil-fuel and mineral-forming processes that should be of interest to many countries. A meeting to solicit industry's views is being considered.

BOM:

A long and varied association with industry has evolved at BOM. Currently, there are cooperative arrangements with industry for 144 specific activities

ranging in content from simple exchange, to technical information exchange, to joint planning, to research, to in-mine testing of proposed technology. In addition, cooperative arrangements with 12 industry associations are now in force. The BOM continues to encourage inquiries on cooperative research without actively soliciting joint projects.

The Committee on Mineral Technology Development Options of the NAS/NRC stated that the BOM should: (1) develop and implement cost sharing and cooperative efforts between government and industry and make them more effective; and (2) work closely with industrial research consortia developed by the various mineral industries. These recommendations are being implemented.

Recommendation 5-3: Simplification of Federal Procurement Procedures

---

BOM:

A concerted effort during the past few years has been made to reduce the number and dollar value of noncompetitive contract awards by BOM while still maintaining a strong working relationship with universities and colleges. Both recent legislation and policy directives have emphasized the need for competition. The result is that the normal procurement process has been lengthened, especially for R&D projects. Also, for most projects, universities must now compete against each other as well as against private organizations. Although P.L. 98-72 provides that "unique or innovative" unsolicited proposals need not be announced in the *Commerce Business Daily*, BOM has found that most of the unsolicited proposals received from educational institutions do not meet that exception to the extent that the offerer would be harmed by such an announcement. However, in order to reduce procurement leadtime and to avoid public announcement of proposed actions, BOM will use grants, rather than contracts, for deserving projects. This will also enable the BOM to meet its responsibility under the President's program to strengthen the capacity of historically Black colleges and universities to provide quality education.

BOM action to date has been minimal, since no simplification can be made until the General Services Adminstration (GSA) imposed procedures can be simplified. If anything, procedures have become more complicated with time.

DEPARTMENT OF TRANSPORTATION

MISSION

Recommendation 1-1: Mission Review

Department of Transportation (DOT) laboratories are primarily test and evaluation facilities with each laboratory's mission tailored to meet specific needs of an operating administration that deals with a single mode of transportation. The Transportation Systems Center (TSC), however, has as its mission the performance of study and analysis functions for the entire Department through annual program agreements (providing the funding to support the activities) with all of the major DOT organizations. Most of DOT's laboratories have recently been reevaluated and restructured, where necessary, to ensure consistency with evolving program goals. For example, as part of its evaluation of the Transportation Test Center (TTC), the Federal Railroad Administration (FRA) redefined the TTC mission to include broader transportation and other research and test issues, especially by non-government sponsors. At the same time, the "care, custody and control" of the entire laboratory facility was contracted to the private sector. Only safety-related railroad research continues to be sponsored by FRA at TTC.

On March 28, 1984, the Secretary appointed a Science and Technology Advisor for the Department. This action is in keeping with one of the recommendations of the President's Private Sector Survey on Cost Control which recommended that DOT should create, through the Office of the Secretary, an entity responsible for R&D policy and goal-setting, and monitoring. The newly appointed Science and Technology Advisor will be conducting a review to assure that recent evaluations/study recommendations are formalized and reflected in new laboratory mission statements and performance goals as part of a comprehensive assessment of departmental R&D programs. With respect to TTC, the FRA will continue periodic formal reviews with the private sector operator to assess the need for any required changes in the TTC mission.

It is anticipated that recommendations will be provided to the Secretary in the near future by the Science and Technology Advisor concerning departmental oversight of all DOT research and development activities. Depending on secretarial decision, an impact on all "mission" and "management" recommendations can be anticipated.

Recommendation 1-2: Size of Laboratory

The operating administrations of DOT have established systems through the budget process for the allocation of resources for all of their components, including the laboratories. Changes in the size of laboratory staff are dependent on assigned workload and overall personnel allocations. Requests for additional allocations are evaluated and if fully justified, temporary adjustments are made. Several laboratories are currently reviewing the size and composition of their staffs and taking actions to cut back

in certain areas and/or hire in others. For example, the Federal Aviation Administration's (FAA's) Technical Center has reduced functions not considered essential to the National Airspace System Plan and enhanced its role in the testing and evaluation of new computers and automated systems.

The Transportation Systems Center's staffing and skill mix are a function of its mission and workload because all funding is provided by various DOT organizations from their approved programs and in support of their specific needs. TSC is also subject to personnel ceiling limitations set by the Department, the Office of Management and Budget (OMB), and the Congressional budget process. There have been substantial reductions in force (approximately 20% of the work force) at TSC during the past 2 years, in response to Administration priorities, needed skill mix changes, and funding reductions.

A formal review of the first year of operation of TTC by the private sector indicated a misalignment of the labor skill mix based on the expected testing and revenues for the second year of operation. The private sector operator was free to implement the necessary adjustments based on anticipated mission requirements.

The Department will evaluate its use of established systems to control and monitor the size of the laboratories, increasing or reducing staff as appropriate, seeking all suitable opportunities for defederalization, and considering laboratory closing consistent with diminishing mission requirements.

FUNDING

Recommendation 3-1: Multiyear Funding

DOT receives no-year funding on an annual basis. Congress appropriates approximately 50% of the DOT pay raise requirements. The remaining pay raise cost is absorbed within DOT by reducing other object classification areas, such as overtime, travel, supplies, materials, and equipment.

Instability due to annual appropriation is not a problem. No recommendation is made for 2-year funding. DOT supports full pay raise supplemental.

No agency actions are required. OMB and Congress must approve pay raise supplemental.

Recommendation 3-2: Discretionary Funds

The DOT generally receives no discretionary funds. The concept is being reviewed along with other Grace Commission recommendations on R&D management.

The concept of discretionary funding is supported, but without establishing a specific percentage, since the mission and modus operandi of the laboratories vary with each Administration.

Each of various Grace Commission and Packard Report recommendations for DOT is currently under study. A decision as to the implementation of discretionary funding will be made in the context of these recommendations and in the context of other related management issues.

Plans are to resolve these issues in time for the next budget cycle.

Recommendation 3-3: Carry-over Funding

Appropriations for research and development are no-year funds. No change in funding is necessary to meet the recommendation. No action is required.

MANAGEMENT

Recommendation 4-1: Oversight Function

Several DOT laboratories have already established internal and/or external review committees. For example, TTC has set up several industry committees, including university advisory groups, to review proposed work and evaluate the quality of the reports, sponsor technical conferences, and support industry implementation of the results. In 1983, the Federal Highway Administration's (FHWA's) Fairbank Highway Research Center expanded arrangements for obtaining more extensive input from state highway agencies. Micromanagement does not appear to be a problem in DOT, and the committees have not been involved in this issue.

Recommendations will be presented to the Secretary in the near future for strengthening agency oversight of all DOT research and development activities. With respect to the laboratories, specific attention will be addressed toward assuring conformance with the thrust of this panel recommendation.

Recommendation 4-2: Greater Reliance on Peer Review

Basic research is not performed or funded at DOT laboratories.

Recommendation 4-3: Finite Term for Laboratory Director

DOT laboratory directors are held accountable, and their position descriptions and performance standards stress accountability and productivity. No finite term of appointment is formally addressed. The private sector operator of TTC has sole responsibility for the quality and productivity of the Center. Performance will be judged on the business he attracts from the private sector and on the ability to carry out specific research tests under the terms of task order contracts issued by FRA. Conditions for contract termination are specified in the 5-year facility contract which also has an option for 2 additional years.

DOT plans to continue the established system of performance evaluation to assure accountability, quality, and productivity. Implementation of this recommendation with respect to finite terms is currently being studied.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

The Department of Transportation, through its modal administrations, strives to keep the academic community involved in various transportation programs. The U.S. Coast Guard's R&D Center has had cooperative

efforts in the fire research area. The Coast Guard Academy facilities and faculty are shared with the academic community. The Federal Highway Administration has considerable involvement with existing programs of contract research by which states (with Federal aid) have close ties between state highway agencies and local universities. The Federal Aviation Administration, at its Civil Aeromedical Institute in Oklahoma City, allows regular use of its facilities for testing and evaluation of equipment and is encouraging further use of its facility by the university community and industry. The Research and Special Programs Administration, through its Transportation Systems Center in Cambridge, Massachusetts, has an excellent technical and contractual relationship with universities covering a variety of research subjects dealing with the entire transportation community. TSC has been the lead monitor for many DOT research contracts with such institutions as Worcester Polytechnical Institute, University of California at Berkeley, and the Massachusetts Institute of Technology.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

---

Technology sharing is basic to the responsibilities of the Department. The Department of Transportation Act of 1966 specifically directs the Secretary to "promote and undertake development, collection, and dissemination of technological, statistical, economic and other information..." and to "...consult and cooperate with state and local governments." All elements of the DOT respond to this mandate and have set up a variety of mechanisms for the sharing of Federal technology, including: the dissemination of special "information packages" and newsletters, conducting technical conferences and planning meetings, the use of technical advisory and review committees, and the establishment of technology-transfer centers.

Each DOT operating administration typically has its own set of research programs and consultation mechanisms, often managed by an Associate Administrator for Research and Development or a similarly titled official. The various technology and knowledge sharing programs within DOT are structured to support the specific functions of each of the operating administrations. To assure support of broader departmental objectives, the Office of Intergovernmental Affairs' Technology Sharing Division in the Office of the Secretary of Transportation (OST) provides cross-program coordination. The focus of the OST work is on integrating the various operating administration efforts, providing needed policy support to them, and reaching constituent groups not contacted by the other elements.

The Department of Transportation manages nine laboratories engaged in R&D activities. The responsibility for technology transfer involving the laboratories rests within each of the operating DOT administrations. In support of the Stevenson-Wydler Act, the Office of Research and Technology Application (ORTA) contacts have been identified for each laboratory. Departmental oversight and coordination is provided by the Technology Sharing Program under the Assistant Secretary for Governmental Affairs

within the Office of the Secretary. Collaborative efforts between the laboratories and universities are encouraged.

Industry support of U.S. Coast Guard fire research is being carried on through equipment donations and services. The Federal Aviation Administration has many collaborative efforts in terms of equipment testing and direct funding support at both its Technical Center in Atlantic City, New Jersey, and Civil Aeromedical Institute in Oklahoma City, Oklahoma. The aviation industry regularly uses these facilities for test and evaluation of aircraft safety equipment as well as of communications, navigation, and other electronic devices. The Federal Highway Administration's Fairbank Laboratory in Langley, Virginia, has made it standard practice to establish cooperative agreements with industry and universities. The FHWA recently signed a contract with the American Iron and Steel Institute to conduct on a cost-sharing basis major experiments in its structures laboratory for the improvement of design concepts for steel bridges.

The Federal Railroad Administration's Transportation Test Center in Pueblo, Colorado, was turned over to the private sector in 1982 through a facilities contract for the "care, custody and control" of the test center. The R&D interactions of the TTC are facilitated through the use of industry oversight committees and consultants, as well as through the use of collaborative research programs. In these programs, both in-kind services and funding resources are obtained from industry. A "user fee" mechanism is applied to all non-Federal work done by the contractor in order to prevent unfair competitive practices in seeking outside work.

The Transportation Systems Center in Cambridge, Massachusetts, is a recognized leader in the study and analysis of transportation issues and problems. In the course of these studies, TSC creates, collects, and disseminates transportation-related data and information. TSC continually communicates the results of its activities, especially to colleges, universities, and the transportation community. This is accomplished through the Center's Office of University Research and Technology Sharing.

The DOT will continue to explore further cooperative arrangements with universities to utilize its laboratory facilities. The DOT will also explore new possibilities for cost-sharing research programs with private industry using its laboratory facilities.

Recommendation 5-3: Simplifying Federal Procurement Procedures

---

The DOT would welcome a simplified and liberalized mechanism for collaboration between R&D laboratories and universities or various industries to streamline cooperative R&D efforts. The strict provisions of the Federal Procurement Regulations (FPR), coupled with strictly structured funding procedures, inhibit this procedure.

At present, interactions between DOT laboratories and industry/universities are generally limited to specific contractual relationships presented in accordance with competitive FPR guidelines. Little opportunity exists for negotiated agreements, for joint R&D efforts partially funded by government and partially by industry, or for other innovative arrangements.

All service support contracts at the Transportation Test Center, formerly administered by the Federal Railroad Administration (FRA), are now executed solely through a private sector contractor. The contractor is not encumbered by Federal procurement procedures except where Federally funded research is concerned. The provision for obtaining the research needed by the FRA is incorporated into the basic facilities contract. This procedure greatly facilitates FRA contracting for research with the TTC operator, who represents the railroad industry.

ENVIRONMENTAL PROTECTION AGENCY

MISSION

Recommendation 1-1: Mission Review

The Environmental Protection Agency (EPA) places a high priority on maintaining current functional statements for its laboratories which clearly define their missions. From July 1981- July 1982, the Office of Research and Development conducted an in-depth study of the organization of EPA laboratories and decided that the current organizational structure was appropriate; however, EPA continues to incrementally review and revise the mission and organization of its laboratories to reflect changes in program priorities. In addition to continually reviewing and revising the mission of its laboratories, the EPA Office of Research and Development (ORD) plans to establish a Strategic Planning Staff whose function will be to study emerging environmental problems and determine: (1) whether research is warranted, (2) where research efforts should be focused, and (3) perhaps even how the research results would relate to current or proposed policy direction. The laboratories' missions will be redefined as necessary to accommodate the research efforts identified by the Strategic Planning Staff.

Recommendation 1-2: Size of Laboratory

EPA constantly reviews the size of its laboratories in relation to their missions. The Agency uses the flexibility available through the personnel system to relocate the work force as appropriate. Every attempt is made to vary the size of laboratories on the basis of long-term, major program shifts, rather than as a reaction to changes in one budget year. Experience has shown that there can be a resurgence in a program following a short-term reduction in resources. Because of the problems in staffing up or down, every effort is made to look at the long term. However, occasionally the budget process does produce major fluctuations in the resources available to support laboratories, and the size of the laboratory staff must be adjusted accordingly.

FUNDING

Recommendation 3-1: Multiyear Funding

EPA has never received a true multiyear appropriation. The Office of Research and Development currently receives two separate appropriations on an annual basis. One is for salaries and expenses (S&E), which is a 1-year appropriation and covers all the costs associated with conducting the in-house program. The second appropriation supports the extramural research and development program (R&D) and is a 2-year appropriation. However, this 2-year appropriation only contains sufficient funds to cover 1 year's expenses. A new 2-year appropriation is enacted each year. Pay raises must be covered by the S&E appropriation.

EPA wholeheartedly supports the recommendation that funding be authorized on a predictable basis. Resource instability and unpredictability are problems that have hampered EPA in its efforts to plan and implement a well-integrated research program. If fluctuations in the level of R&D resources could be eliminated, or at least substantially reduced, the R&D program would be greatly enhanced. However, requesting and receiving an R&D appropriation only every 2 years may not really help solve this problem. Stability over a longer period than 2 years is necessary, yet having the flexibility to ask for budget increases to support new program requirements is also desirable.

Funds also should be appropriated to cover pay raises. Agencies should not be required to fund pay raises from resources earmarked for other purposes.

Congress must approve these changes.

Recommendation 3-2: Discretionary Funds

The primary mission of EPA's laboratories is to support the Agency's regulatory program. Scarce resources leave very little flexibility to engage in research other than that required to support the Agency's client offices. EPA has an exploratory research program of $15 million to examine emerging environmental problems. These funds support research at colleges and universities in the form of grants and cooperative agreements. Also, 1% of the R&D appropriation is set aside to fund the Small Business Innovation Research Program. These programs provide a meaningful long-term research effort.

EPA generally supports the recommendation; however, support of the Agency's regulatory program must continue to be top priority.

The Agency should provide the laboratory directors greater flexibility in planning the projects to be conducted in their laboratories.

In fiscal year 1985 laboratory directors will have increased flexibility in conducting projects. Headquarters has reduced resource reporting requirements to allow laboratory directors greater discretion in managing the resources of their laboratories. To the extent that resources permit, in future years laboratory directors will be provided even greater discretion in planning and executing the research programs of their laboratories.

Recommendation 3-3: Carry-over Funding

EPA has a 2-year appropriation to support its extramural research and development program. To the extent that funds are available, the Comptroller allocates carry-over to Agency programs based on justifications of need and Agency priorities. Because of the time required to analyze needs and determine priorities, carry-over funds are frequently not made available to the laboratories for obligation until late in the fiscal year.

EPA supports this recommendation. Currently the Agency has the mechanism in place to enable the timely obligation and disbursement of carryover funds. However, because of the limitation of resources, the Agency must carefully consider competing priorities and allocate available carryover funds as required to best support the Agency's mission.

MANAGEMENT

Recommendation 4-1: Oversight Function

This recommendation is already being implemented at EPA. The Office of Research and Development reviews each research program at least once every 2 years and reviews proposed research on an as-needed basis. Review panels include research leaders from EPA and scientists from other government agencies, the academic community, and industry. This review process serves to evaluate how ongoing research is progressing and how proposed research is to be performed, that is, how scientifically sound the technical approach or experimental design is. This system assures that research funds are providing high-quality products reflecting good science and engineering; it also monitors performance and productivity. Although EPA has an ongoing external peer review process, the Agency has recently taken additional actions to make it even more effective. The peer review process has been decentralized to make it the responsibility of the laboratory director rather than a centralized management responsibility. Within the past 6 months, the Office of Research and Development has examined the delineation of the roles and responsibilities of Headquarters and laboratory management. Changes in management information requirements are being made to implement the appropriate division of responsibilities. These changes will further diminish the potential for micromanagement because the laboratory directors will be held responsible for accomplishments and outputs and overall utilization of their resources rather than being required to account for expenditures at the task or project level.

Recommendation 4-2: Greater Reliance on Peer Review

EPA sponsors research in the scientific and academic community primarily through two mechanisms which are both peer reviewed. One mechanism is the competitive grants program which was established in 1979 and is administered by the Office of Exploratory Research. Under this program, proposals are solicited each year and grants are awarded competitively based primarily on the recommendations of the scientific peer review panels. Another mechanism is for the individual laboratories to enter into cooperative agreements with the academic or scientific community. Prior to award, all proposals for cooperative agreements are peer reviewed by extramural reviewers who are experts in their field. The Office of Research and Development's policy is to broadly solicit applications and to award grants and cooperative agreements competitively,to the maximum extent practicable. All grants are awarded competitively, and any decision to award a cooperative agreement on a noncompetitive basis must be justified in a memorandum that is included in the project file.

Recommendation 4-3: Finite Term for Laboratory Director

EPA agrees that the laboratory directors must be held accountable for the activites in their laboratories. EPA laboratory directors are all members of the Senior Executive Service (SES) who have performance contracts that hold them completely accountable for the productivity of the laboratory. SES procedures allow a great deal of flexibility to reassign members as necessary and appropriate; however, this recommendation will be given further consideration.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

The 14 EPA/ORD laboratories are located on nine sites, all of which are within a short commuting distance of university campuses. Cooperative agreements with the institutions are in force.

The unique Clinical Studies Facility of the ORD/Office of Health Research is located adjacent to the University of North Carolina School of Medicine. The cooperative agreement stimulates collaborative programs and permits use of the facility by university staff.

Negotiations with the Coordinating Research Council of the Air Pollution Research Advisory Committee to utilize the ORD mobile source facilities at Research Triangle Park for a series of studies are currently in process.

An air pollution control research facility (Limestone Wet Scrubber) at Research Triangle Park has been utilized extensively by an industrial organization during the past several years.

The Unique Oil and Hazardous Material Spill Simulator Facility in Edison, New Jersey, has been made available to both university and industrial research teams.

The EPA Fluid Modeling Facility is made available to students at North Carolina State.

The University of Cincinnati operates ORD's Test and Evaluation Facility under contract. Additionally, graduate students from the University are provided the opportunity to conduct research at the facility.

In addition to ongoing activities aimed at encouraging university and industry access to Agency facilities, EPA recently implemented a new "Senior Visiting Scientists" program. This program is designed to bring some of the leading names in environmental science from universities and other institutions into EPA laboratories to conduct research. These scientists will help promote those areas of environmental science that are most significant to the Agency, and the program will help build closer working relationships between EPA laboratories and leading environmental scientists.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

The automotive industry and EPA co-fund the Health Effects Institute to address studies pertaining to health effects presumed to be induced by automotive emissions.

The EPA Environmental Research Laboratory at Ada, Oklahoma, has been involved in collaborative studies with the American Petroleum Institute concerning land treatment of petroleum processing wastes.

Collaborative programs with industry in the development of pollution control systems (fabric filters, limestone injection technology, sequencing batch reactors, mobile treatment facilities, hazardous waste disposal technologies) have been a major component of the EPA research program.

Recommendation 5-3: Simplifying Federal Procurement Procedures

EPA is required to comply with the Federal Acquisition Regulation (FAR) and other government policies on procurement but, to the extent that there is any flexibility, the Agency is making every effort to simplify and streamline the procurement process. In 1982, EPA established a Procurement Review Task Force in response to Executive Order 12352 directing reforms in government procurement. The Task Force spent 10 months studying the problems surrounding the EPA procurement process, making recommendations for improvement, and effecting their implementation. Some of the results of that project are increased flexibility, elimination of redundancies and inconsistencies, reduced leadtimes, increased accountability, reduced paperwork, cost savings for the government and the private sector, and overall simplification of the procurement process within the Agency. The Office of Research and Development is in the process of revising Agency policy on management approval levels for procurement to provide the laboratory directors greater flexibility and authority than they currently have.

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

MISSION

Recommendation 1-1: Mission Review

The National Aeronautics and Space Administration (NASA) annually prepares a long-range plan that defines and describes the objectives and programs for the agency and each of the centers (laboratories). In the past 3 years, increasing attention has been given to the contributions, roles, and well-being of the various elements of the NASA institution.

In 1981, a top-level review led to the consolidation of two smaller centers with two larger ones based on a determination of the best way to carry out related missions with available resources. The same year, three Associate Administrators, the principal program executives of NASA, were given responsibility for the institutional management of the centers. Included in their responsibilities is the advocacy and fostering of roles and missions for their centers.

The budget submission each year displays the missions and programs of the centers and provides the regular opportunity to review them. Major program initiatives, such as the Space Station, also require top management to look at the distribution of missions.

In 1983, NASA instituted a formal goals and objectives process. The agency goals and objectives were adopted with the participation and input of the center directors who were then instructed to formulate objectives supporting and elaborating on those of the agency. This year, NASA managers are reviewing the 1983 objectives for updating and modification. The underlying purpose of the process is to keep agency efforts focused on priority missions.

Recommendation 1-2: Size of Laboratory

NASA planning and budget processes include analysis of center manpower needs. There is an effort to avoid small fluctuations in response to normal program expansion or reduction so that a critical mass of relevant R&D competence can be maintained. This is often accomplished by adjusting the size of contractor support work forces.

However, the size of centers is responsive to major changes in program emphasis. NASA's overall civil service permanent complement has fallen from the Apollo program peak of over 35,000 in the late 1960s to under 22,000 today. Within that level, individual centers show marked differences based on major program changes. Marshall Space Flight Center, with a large launch vehicle and engine development mission, dropped from a high of over 7,000 to just below 3,500 now. Lewis Research Center dropped from 5,000 to 2,750 as some of its specialized programs declined in scope.

Reductions like these and the closing or consolidation of centers demonstrates conclusively that preservation of each laboratory has not been a mission.

FUNDING

Recommendation 3-1: Multiyear Funding

NASA has annual appropriations available for 2 years for its basic and applied research. The research program is a relatively small part of the agency's total program and is not specifically identified.

The basic and applied research activities are conducted in a manner that is synergistic with many of the developmental activities of the agency. To break out these research and development activities in a separate appropriation probably would subject them to more scrutiny in an environment not related to the overall mission of the agency and might result in more rather than less instability in the funding process. The 2-year availability of appropriated funds insulates against short-term instability, and continuing appropriations have not been a major problem to basic and applied research activities.

Recommendation 3-2: Discretionary Funds

Discretionary funding allocated to center directors constitutes approximately 4% of total in-house basic and applied research funds. The funding supports independent research, generally of a highly innovative nature, for which small expenditures are sufficient to establish whether there should be sustained effort or not. Accordingly, some activities "graduate" to regular R&D funding.

As recently as 1983, one center had discretionary research results cited for IR-100 Awards as "two of the 100 most significant new technical products of the year." The center directors make annual reports of discretionary fund activities to the Deputy Administrator, who subsequently relates funding levels to the performance of the centers. The reports are shared by all centers. The directors are authorized to fund both in-house and out-of-house work.

MANAGEMENT

Recommendation 4-1: Oversight Function

NASA has an Advisory Council and a network of advisory committees reporting to it. The members are eminent people outside NASA in aerospace industry, academia, and other areas in which they are in a position to give NASA advice. One of the concerns of the Advisory Council and its committees is the status of the center programs.

NASA will look to the Advisory Council for more activity in overviewing the continuing excellence of the centers. During the past year, the Space Systems and Technology Advisory Committee, headed by Robert L. Walquist of TRW, has been conducting a study of the "center of excellence" in roughly a dozen areas of technology at the research centers. They have

focused on the availability and quality of the center people, facilities, and programs in these specialized areas. The committee will report to the Advisory Council in the near future.

Recommendation 4-2: Greater Reliance on Peer Review

The NASA Advisory Council system, including its committees, provides an overall review of the agency's research and technology programs by outside authorities who are peers of NASA's researchers and research managers. Findings and recommendations are fed into the planning and budgeting processes. In addition, there is formal peer review of scientific activities.

INTERACTION WITH UNIVERSITIES, INDUSTRY, AND USERS OF RESEARCH RESULTS

Recommendation 5-1: Access to Federal Laboratories

Since its establishment in 1958, NASA has sought both advice and assistance from the university and industrial communities in determining and conducting research into problems of flight within and outside the Earth's atmosphere. This mutual effort to add to national strength has resulted in extensive and diversified relationships between university and industrial personnel and NASA research laboratories.

NASA has major interfaces with two closely related communities: aeronautics and space. In the area of aeronautics, universities and industry make extensive use of NASA ground-based facilities through a number of existing mechanisms. This program is working well and major changes are not planned. However, exploratory, four-way discussions are in progress among the following parties: (1) NASA aeronautics laboratories, (2) universities seeking to strengthen their graduate aeronautical engineering programs, (3) aircraft manufacturers interested in upgrading their engineering and design capabilities which will include not only traditional model test facilities, but also enable industry access to NASA's newly established supercomputer-based computational facilities, and (4) state government economic development agencies taking an interest in local aeronautics firms as part of their efforts to utilize science and technology for industrial development. These discussions are focusing on a model program that would combine graduate study with practical experience in both NASA field centers and industry design and production groups. If successful, such a program could be expanded to include other disciplines, industries, universities, and laboratories.

In the area of space, NASA facilities are physically located both in space and on the ground. The use of these facilities for *space technology* development has recently been addressed by a special study group, and the resulting actions are described under the NASA response to Packard Report Recommendation 5-2. The use of the NASA space facilities for *scientific research* is determined by open competition, and no changes in this area are appropriate or planned. However, the use of NASA ground facilities by the university and industrial scientific research communities

is an area that can be enhanced. It is planned that each NASA center will publish a document describing its applicable ground facilities in order to enhance their use by the total research and technology communities. The use of the facilities by such outside groups will be made a basis for the evaluation of the performance of each of the NASA laboratories.

NASA's university program is conceptual in nature and is a collection of diverse activities, which individually and collectively contribute to the agency's mission. The principal and most visible direct interaction between NASA and the university community is the support of university research and development projects. In fiscal year 1984, NASA funded approximately $230 million to educational institutions to conduct research in aeronautics and space science. Of this total, approximately 10% was used to update university instrumentation.

While sponsored research is the single largest activity fostering interaction and access to facilities and research programs, NASA is committed to discovering, developing, and facilitating new relationships with the academic community at all levels. To meet this objective, NASA has initiated a number of programs targeted at specific populations within the educational community. For clarification purposes, they are categorized as (1) university programs, (2) personnel programs, and (3) external education programs.

NASA sponsors a number of specific university programs that facilitate NASA/university interaction. Each year the agency provides opportunities for individuals to do post-doctoral research at NASA centers. This program is part of the National Research Council's Resident Associateship Program. In cooperation with the American Society of Engineering Education, NASA centers invite faculty members from across the nation to be guest investigators at NASA facilities during each summer. Beginning in 1980, the agency initiated a program to provide research opportunities for graduate students to conduct their thesis research at NASA facilities. Many additional programs, such as the Joint Institute for Advancement of Flight Sciences, Get Away Special, University Consortium, and Space Shuttle Student Involvement Project, aim to discover and develop talent and to increase involvement between NASA and the university community.

NASA continues to take advantage of the numerous personnel programs within the Federal government to foster interaction between students and faculty at all levels in the educational community and NASA laboratories. These programs, while affected by full-time equivalency limitations, still provide an excellent mode of fostering interaction. The cooperative education program continues to be a source of discovering new talent. NASA centers utilize co-op programs at the community college, baccalaureate, and post-baccalaureate levels in areas of secretarial science, engineering technology, engineering, and science disciplines. Additional programs, such as the Intergovernmental Personnel Act, Summer Employment Upward Bound, Presidential Management Intern, and the Pre-College Trainee programs, to name a few, all contribute toward multilevel interactions between NASA and the educational community.

Another important component in fostering relationships with the educa-

tional enterprise is the NASA External Educational Services Program. Targeted primarily at the primary and secondary education level, information on NASA's missions and results is provided to students and teachers in their academic setting to foster an interest in mathematics, science, and engineering. In addition, many NASA centers have developed teacher resource rooms that provide public-school teachers an inexpensive avenue to obtain films, video tapes, pictures, and information to supplement school curricula.

In addition to these activities, a joint NASA/National Academy of Sciences study group has been formed to recommend ways by which NASA-university relations can be enhanced. The report of this group is scheduled for the Fall of 1984. The recommendations will be evaluated and implemented if appropriate.

Recommendation 5-2: R&D Interaction Between Federal Laboratories and Industry

---

NASA has historically had close and extensive interactions between its laboratories and the aeronautics industry. This program is working well, and major changes are not planned. A special agency study, however, has recently been completed to determine how NASA can apply its experience in aeronautics to enhance R&D interactions with the aerospace industry. The study recommended 14 specific actions that, on April 3, 1984, were endorsed by the Administrator as agency policy. Particular attention will be given to establishing increased uses of NASA facilities in space, such as the Space Shuttle and the Space Station, by industry for technological development.

In addition, NASA is seeking new opportunities for cooperation with state government initiatives linking science and technology with industrial development. Several such opportunities for joint NASA-university-industry research and development programs, drawing partial support from state industrial-development sources, have been identified. "Centers of excellence" established at or in conjunction with universities under state auspices provide the focuses for most of these programs. The programs themselves would have the potential to facilitate intersectoral communication and technology transfer in aeronautics, space industrialization, and the non-aerospace use of NASA-developed technology.

The NASA Technology Utilization Program, an agency-wide effort involving and drawing on all of NASA's laboratories and R&D programs, continues to provide a variety of means for U.S. industry access to NASA technology. The program's management has, over its 20-year history, learned that it must rely on private sector industrial involvement to facilitate non-aerospace use of such technology. While much of this activity involves what might be called the "retailing" of specific items for individual products or processes, the program is now concentrating more heavily on "wholesaling," involving in some cases the transfer of generic capability, so that the acquiring industry can undertake a wide range of applications. The current directions and achievements of the NASA Technology Utilization Program are set forth in NASA's annual *Spinoff* publication.

Acronym Glossary

AD	Area Directors (USDA)
ANL	Argonne National Laboratory (DOE)
ARS	Agricultural Research Service
ASB	Army Science Board
BAO	Boulder Atmospheric Observatory (NOAA)
BNL	Brookhaven National Laboratory (DOE)
BOM	Bureau of Mines
CIMAS	Cooperative Institute for Marine and Atmospheric Studies (NOAA)
CIMMS	Cooperative Institute for Mesoscale Meteorological Services (NOAA)
CIRA	Cooperative Institute for Research in the Atmosphere (NOAA)
CIRES	Cooperative Institute for Research in Environmental Sciences (NOAA)
CODAR	Coastal Ocean Dynamics Applications Radar (NOAA)
DARCOM	Army Materiel Development and Readiness Command
DOC	Department of Commerce
DOD	Department of Defense
DOE	Department of Energy
DOT	Department of Transportation
EPA	Environmental Protection Agency
FAA	Federal Aviation Administration
FAES	Foundation for Advanced Education in the Sciences (NIH)
FAR	Federal Acquisition Regulation
FPL	Forest Products Laboratory
FPR	Federal Procurement Regulations
FRA	Federal Railroad Administration
FS	Forest Service
GMCC	Geophysical Monitoring for Climatic Change (NOAA)
GOCO	Government-Owned Contractor-Operated
GSA	General Services Administration
IPA	Intergovernmental Personnel Act
IR&D	Independent Research and Development Program (DOD)
IRI	Industrial Research Institute
JILA	Joint Institute for Laboratory Astrophysics (NBS)
JIMAR	Joint Institute for Marine and Atmospheric Research (NOAA)
JISAO	Joint Institute for Study of the Atmosphere and Ocean (NOAA)
LINAC	Linear Accelerator
LMC	Laboratory Management Council (DOE)
LMTF	Laboratory Management Task Force (DOD)
MFAC	Marine Fisheries Advisory Committee (NOAA)

NACOA	National Committee on Oceans and Atmosphere (NOAA)
NAS	National Academy of Sciences
NASA	National Aeronautics and Space Administration
NBS	National Bureau of Standards
NCI	National Cancer Institute
NIH	National Institutes of Health
NMFS	National Marine Fisheries Service (NOAA)
NOAA	National Oceanic and Atmospheric Administration
NPS	National Program Staff (USDA)
NRAC	Naval Research Advisory Committee
NRC	National Research Council (NAS)
NTP	National Toxicology Program (NIH)
NURP	NOAA Undersea Research Program
OMAR	Office for Medical Applications of Research (NIH)
OMB	Office of Management and Budget
ORD	Office of Research and Development (EPA)
ORNL	Oak Ridge National Laboratory (DOE)
ORTA	Office of Research and Technology Application (DOC,DOD,DOT)
OSD	Office of the Secretary of Defense
OST	Office of the Secretary of Transportation
OTTO	Ohio Technology Transfer Organization (NOAA)

THE PROBLEM OF BIG PROBLEMS REVISITED*

Alvin M. Weinberg
Institute for Energy Analysis
Oak Ridge Associated Universities
Post Office Box 117
Oak Ridge, Tennessee 37830

Thirty years have passed since I first speculated on the future of the National Laboratories. To quote from my "Future Aims of Large-Scale Research":

> "Today's big scientific-technological problems cannot be expected to remain forever to challenge the institutions that were mobilized to cope with these problems...the (ultimate) viability of (these) institutions depends upon, and is limited by, existence of new problems of magnitude, scope and interest sufficient to challenge them adequately....(They) and their sponsoring agencies must inevitably be prepared to move into areas outside their original interests."[1]

Time has largely borne out these predictions, at least as far as the world's nuclear laboratories are concerned: most of the laboratories have taken on jobs unconnected with nuclear fission. In this essay I shall examine the history of this redeployment of the National Laboratories, particularly in the United States. Where has it been successful, where less successful? Do the areas the laboratories have moved into possess the social validity that merits support, and the scientific characteristics that match the capabilities of the laboratories? And can the laboratories continue to find new Big Problems to follow this generation's Big Problems--or will the laboratories lapse into a colorless survival, doing whatever a bureaucrat in Washington can pay for, irrespective of its significance in the resolution of serious social questions? My time horizon will be a long one, perhaps even a century, in keeping with the 100th anniversary of Daimler-Benz which we are celebrating.

The war-born Atomic Energy Laboratories represented the flowering of the era of Big Science. Though Ernest Lawrence's cyclotron laboratory at Berkeley, and perhaps the astronomical laboratories were harbingers of Big

*Contribution to the commemorative volume of Daimler-Benz, 1985.

Science, the massive attack on nuclear energy by dedicated laboratories marked the full blooming of the style of Big Science. This style addressed big problems, used big equipment, and made big demands on the society that supported it.

The fate of the big applied nuclear laboratories might, in a curious way, be linked to the future of other institutions of Big Science--particularly the high energy physics laboratories. High energy physics, the Big Science aimed at elucidating the ultimate constitution of matter, had many of its roots in the quest for practical atomic energy. It was, after all, the Atomic Energy Commission that raised the money from Congress for, and then "owned," Brookhaven, the Fermi Laboratory, and the Stanford Linear Accelerator. Indeed, the Atomic Energy Act of 1954 gave cognizance to the AEC for high energy physics, largely because, at the time the act was framed, the connections between practical atomic energy and high energy research seemed to be closer than we would now judge it to be. No wonder that Professor John Wheeler, a distinguished theoretical physicist, quipped at a meeting of high energy physicists, "Nuclear fission is like sex. It is a subject not openly discussed in a gathering of high energy physicists. But each of us deep in his heart knows that were it not for fission, no less than sex, none of us would be here!" I suspect that this connection remains in the public's and politicians' minds, if not in the scientists'; the fate of nuclear energy and of the institutions directly concerned with its development to some extent may bear on the support and health of such fields as high energy physics.

Have the Nuclear Energy Laboratories Achieved Their Original Missions?

Most of the original nuclear energy laboratories have redeployed, at least in part, around problems unconnected with their original missions. Has this redeployment been premature? Have the laboratories achieved their original mission, which was the development of safe, practical, and economical nuclear energy? Of course, achievement of mission is only one reason for redeployment. If, as in Sweden, a political decision puts an end to nuclear power, then Studsvik has no choice but to disband or to engage in matters other than nuclear energy development. Moreover, much of the nuclear energy development has passed into the commercial sphere. Reactor manufacturers such

as KWU, General Electric, and Westinghouse possess powerful research establishments that are as capable in many ways as are the National Laboratories. Even if major development in nuclear energy remains to be done, are the National Laboratories the right places in which to conduct the development?

Before we can identify what still remains to be done in nuclear energy, we must examine nuclear energy's successes, its failures, its prospects. Since this is a topic that has been much discussed, I shall be brief, and shall focus on those aspects of the matter that are relevant to the question, "Have the National Laboratories finished their original job?"

Nuclear energy today is doing well in some countries, poorly in others. Though, by 1990, some 10 percent of the world's primary energy and 30 percent of its electricity will be generated in nuclear reactors, nuclear energy has, in most Western countries, become a source of political strife. No new reactor has been ordered in the United States since 1978. Sweden is scheduled to abandon nuclear energy by 2010, despite the generally superb operating record of its reactors, which now supply more than 40 percent of that country's electricity. By contrast, nuclear power is flourishing in France, in Japan, and in the Soviet Union. France and Japan, neither of which has indigenous fossil fuel, continue their massive deployment of nuclear reactors: France will have, by 1990, some 60 reactors which will produce 65 percent of that country's electricity; Japan, 35 reactors, accounting for 25 percent of its electricity. In between are countries like the Federal Republic of Germany, which now has 20 reactors producing some 24 percent of its electricity, but in which opposition to nuclear energy is serious and strident.

Where nuclear power has encountered the most difficulty, as in the United States, three interrelated factors are responsible. First, electricity demand has not expanded as fast as was expected in the early 1970s, and so several partly built reactors have been delayed or cancelled. Second, many nuclear reactors in the United States cost far too much; and, third, largely because of the accident at Three Mile Island, about half of the public doubts that nuclear energy is safe. The public's fears are translated into very burdensome regulation of nuclear power; and in the United States this, coupled with a fragmented utility industry and high interest rates, has led to outrageously

long construction schedules and some brutally expensive plants. In addition, the delay in sequestering high level wastes permanently has added to the public's dislike of nuclear energy.

All of this comes at the same time as environmental activism has become a powerful political force. Though one can make a strong case for nuclear power being one of the cleanest energy sources, environmental politicians choose not to accept this view: for them nuclear power is unacceptable largely because one cannot rule out, totally and absolutely, the possibility of a very large accident; and because high level wastes still are in temporary, not permanent, storage. Nuclear power, despite its many technical successes, remains an energy source under seige: in every Western country political forces are actively trying to stop it. In Denmark and Austria, they have succeeded; in the United States, the anti-nuclear forces have all but succeeded, though in this they have been helped by the extraordinary escalation in cost of nuclear power plants.

If one judges the success of the nuclear research establishment (and here I include the National Laboratories, private laboratories, universities) by the technical state of nuclear energy, one must conclude that the establishment has achieved a primary technical goal--competitive nuclear power. Most nuclear reactors operate reliably, and they produce electricity at competitive costs. That nuclear power is often too costly in the United States cannot be blamed on the technology, but rather on the ungainly, sometimes incompetent, handling by managers and regulators of what is a demanding and difficult technology. On the other hand if one judges the nuclear establishment by the degree of acceptance of the technology that it created, then one must conclude that it has failed: nuclear energy, which optimists like me had predicted would take over the world's energy system, has instead become a prime focus of political strife. Granted that the acceptability of nuclear power is largely a social, not a technological matter, its acceptance nevertheless is influenced by the technology. Can one therefore identify technological issues whose resolution would help restore the public's confidence in nuclear power, and which can and should continue to be pursued by the National Laboratories?

What Remains to be Done in Nuclear Energy Development

Three tasks for nuclear energy research still remain before one can claim that the first goal of nuclear energy--development of an acceptable energy source--has been achieved. First, and foremost, the existing fleet of reactors must operate reliably and uneventfully. Probably nothing is more important for the restoration of public confidence in nuclear power than 20 years of accident-free operation of the world's 400-odd reactors. Since these reactors are already built or well underway and are in the hands of utility companies, what the National Laboratories can do to help is limited. Yet these reactors in a way are still experimental devices--none of them has yet reached its design lifetime. By 2000, many of these reactors will be more than 30 years old. Can we identify what weaknesses will develop in these machines by that time, and devise remedies for these weaknesses? If radiation embrittlement of the pressure vessel is their Achilles heel, can one devise practical schemes for annealing the vessel and thus extending its life? Indeed, can one figure out ways of keeping the existing reactors operating long after their design life of 30 or 40 years? The economic benefit could be enormous. Since nuclear reactors cost relatively little to operate, they should produce very cheap electricity once they have been amortized--they are rather like dams in this respect. This realization is only now influencing reactor operators--Calder Hall, which has operated since 1956, has just had its license renewed. Will the Calder Hall reactors last as long as the Newcomen steam engine that finally shut down in 1918? And if electricity from reactors turns out to be cheap because reactors outlive their amortization time, would not the public accept nuclear because it is such a bargain? In brief, the reliable operation of the existing reactors and the extension of their life beyond their design life are central to the acceptance of nuclear energy: insofar as the National Laboratories can help in achieving these goals, they ought to be encouraged to work on their achievement.

A second avenue for continued investigation by the National Laboratories is, of course, waste disposal. I hardly need belabor this point, first because it is so obvious, and second, because the world's National Laboratories are busily engaged in solving the problem. And interesting and useful results are coming from these investigations: in France, over 500 million curies of radioactivity have been immobilized in borosilicate glass; in Australia,

SYNROC, an artificial leach-resistant rock for incorporating radioactivity, has been developed; at Oak Ridge, over a million curies have been permanently sequestered in grout sheets injected under high pressure into shale beds some 300 meters below the earth's surface. Although a tiny amount of radioactivity has leaked from the grout before it had set, I still regard this as a temporary set-back--the million-odd curies in the solidified grout is there forever.

As I look back on my own experience, I would regard our failure to sequester high-level radioactivity permanently in geological formations to be the greatest strategic blunder committed by the nuclear research establishment. We knew enough 20 years ago to immobilize high-level radioactivity in borosilicate glass, and to sequester it permanently in salt formations. Unfortunately, we could not imagine that our failure to actually demonstrate permanent disposal of radioactive wastes would torment the entire nuclear enterprise almost to death. To be sure, we could always argue that there was no technical reason to dispose of the wastes permanently: above-ground storage of spent fuel was adequately safe, and could be relied upon until we finally decided where to put the wastes. Moreover, above-ground storage was cheaper than was development of a geological disposal scheme--what we misjudged was the enormous public concern over our failure to demonstrate permanent disposal. And when, in 1970, we finally decided to sequester transuranic, and then high-level, wastes in a salt mine in Lyons, Kansas, only $25 million (in 1970 dollars) was allocated for the job--some 30 times less than a similar project would cost today! Here was surely a case of penny-wise and pound-foolish--and all of us who were involved must share the blame for allowing the waste disposal issue to become a primary social irritant, despite the availability of adequate technical methods for permanent geological waste disposal.

A third direction for nuclear energy research is the development of inherently safe reactors. Three Mile Island hangs over nuclear energy, an unwanted spectre that we cannot exorcise. To be sure, the probability of a large accident in an existing reactor is very small--of the order of 10^{-4} to 10^{-5} per reactor year, or even lower. But we cannot say that the probability is zero--and opponents of nuclear energy are quick to seize on this tiny possibility of a large accident to damn the entire technology.

Can reactors be designed to be inherently safe, rather than depending for their safety upon active intervention of mechanical and electronic devices, as

well as human operators? In recent years, several ideas for inherently safe reactors have been put forward, notably the Swedish PIUS reactor, and the German modular High Temperature Gas-Cooled Reactor. The possibility of an inherently safe reactor had not really occurred to the nuclear research establishment until very recently. I do not believe we have completed our job until one or even several inherently safe reactors are built: we can then judge whether or not such devices make economic sense. Indeed, I can hardly think of a task that would generate more enthusiasm within the nuclear research establishment than the development of an inherently safe reactor--an ultimate technological fix for the society's somewhat unreasoning, yet perhaps understandable, fear of a large reactor accident!

The three directions for research I have proposed--reliability/longevity, waste disposal, and inherent safety--are aimed at improving the social acceptability of the existing nuclear energy system. Eventually nuclear energy based on the existing light water converters will come to a halt because uranium is relatively rare--unless we can extract that element cheaply from the sea (which contains 4×10^9 tons of uranium), or unless we learn how to build safe and economical breeders. The incentive for such long-range goals must lie, ultimately, in our belief that the world will continue to demand more energy, and that the alternatives to burning uranium will always be inadequate to meet the demand.

The world's current primary energy demand of perhaps 10 terawatt years per year (i.e., 10 TW), hardly seems sufficient for a world 100 years from now. Though some energy revolutionaries claim to see a world of 2085 that uses but 10 TW, most of us would regard this as highly unlikely. China is industrializing, and so is India. Moreover, the world is electrifying: in 1950, 13 percent of the world's primary energy was converted into electricity, today it is 35 percent. If this trend continues (as analysts like C. Burwell predict), then we can look forward to a world in which 50 percent of its primary energy goes through electricity. Even if there is no expansion of total energy, this would mean 5 terawatts of primary energy converted into electricity. At an average load factor of 60 percent, this would require the equivalent of 2500 plants each with a capacity of 1 gigawatt of electricity. Were all of these power plants light water reactors, they would consume some 375,000 tons of uranium per year--an amount that would exhaust the estimated 20,000,000 tons of uranium at $150 per kg in less than 60 years.

then, in a completely orderly sequence of development, one would not build a second generation device until the first generation device has used up a reasonable part of its design life. Failure to observe this principle has been blamed by some for the technical unpleasantnesses encountered in the development of the light water reactors. For example, many steam generator failures probably could have been averted had all the lessons learned from early failures been incorporated in later reactors. Thus to have commercially viable breeders 50 years from now, the international community ought to build several first generation exemplars now; the experience we thereby gain will be invaluable for the next generation of breeders. Moreover, the United States ought to participate seriously in this enterprise.

Perhaps the most powerful reason for building breeders now, even though we do not need them, is to learn how long they will last. From the economic standpoint, the one advantage the breeder has over the light water reactor is its cheaper fuel cycle cost; moreover, this fuel cycle cost is essentially independent of the future cost of uranium. If a breeder outlives its amortization time, it becomes a source of extremely cheap energy--a gift, so to speak, which the generation that paid for the breeder bestows upon succeeding generations. The Experimental Breeder Reactor-II in Idaho has just observed its 20th anniversary, and it operates better today than it did the day it started to produce electricity. Thus the outlook for sodium-cooled breeders being more or less "immortal" is surprisingly good--but this must still be regarded as an attractive speculation that can be verified or refuted only with the passage of time and with the construction of several such reactors.

From this long-range point of view, the decision to cancel the Clinch River Breeder in the United States was unfortunate. Not once during the bitter debate that surrounded this decision was the CRBR's role in the study of the longevity of the breeder invoked as a justification for building it. In short, 50 years, a long time as human affairs goes, is hardly enough time to ensure the availability of an all-but-inexhaustible energy source based on uranium; we should be putting in place enough first generation breeders (such as CRBR) now so that the future can know, rather than guess, how long these devices will last.

How can one seriously claim that the National Laboratories have no primary mission in nuclear energy when the development of the breeder, together with its fuel cycle, still remains? Had I the power to allocate our

research resources, I would, within the field of energy research, place the breeder second only to those researches that might help ensure the success of the current era of nuclear energy--reliability/longevity; waste disposal; and inherent safety. Moreover, I would recommend that our approach to breeder development be broadened: the unilateral focus on the LMFBR to the exclusion of all competing breeders was largely a political, not a technical, decision. Perhaps out of the confusion that now surrounds the U.S. breeder program in the wake of the decision to cancel Clinch River might arise a new, broader approach to breeder development, an approach that would surely challenge the National Laboratories to their fullest.

Redeployments I: Project Sherwood

The first major redeployment of the National Laboratories was into controlled fusion--the so-called "Project Sherwood," to use the now discarded code name for this effort. Since the weapons laboratories, even at their inception, had worked on thermonuclear bombs, and had speculated on the possibility of controlled fusion, the establishment of Project Sherwood in 1952 hardly represented a total change in scientific direction.

Project Sherwood aims to create an inexhaustible energy source based on the thermonuclear burning of deuterium. Controlled fusion's ultimate social purpose is therefore the same as the breeder's: each is aimed at an inexhaustible large-scale energy source, the one based on burning the earth's residual uranium and thorium ("burning the rocks"), the other based on burning the deuterium in the oceans ("burning the seas"). Since the social purposes are identical, the two projects have always been in implicit competition, though both the Sherwood and the breeder community have always muted this competition lest it become an excuse for reducing support of both projects by enthusiastic budget cutters.

Were controlled fusion based on burning deuterium feasible and economical, I would agree that it is a better energy source than the breeder. Its raw material, deuterium, is probably easier to extract from the ocean than is uranium from low-grade ores, even though an isotope separation is needed. Though fusion is not without radioactivity, its wastes are much less radioactive than are those from fission. A fusion reactor produces no plutonium: insofar as one is concerned about the risk of weapons proliferation from

breeders, fusion reactors are less threatening. And even a partial meltdown in a fusion reactor had, at least until recently, been regarded as impossible.

These presumed advantages of fusion reactors may prove less decisive as engineers begin to design actual fusion reactors. Though scientific feasibility is yet to be demonstrated for any controlled fusion device, a reactor based on the tritium-deuterium (T-D) reaction requires less stringent conditions than a reactor based on D-D. The fuel for a T-D reactor is lithium, an element that, like uranium or thorium, must be extracted from the rocks, and which is nowhere near as abundant as deuterium. We now realize that fusion reactors will be radioactive, will require special handling, and will probably evoke objections from environmental activists. The induced radioactivity in a fusion reactor persists after the reactor has been shut down. G. Logan of the Lawrence Livermore Laboratory has pointed out that the resulting afterheat could in principle lead to a meltdown of some structure--that fusion reactors no less than fission reactors may not be unequivocally inherently safe.[3] He suggests, therefore, that designers of fusion reactors aim for inherent safety--which would require lower heat loadings, larger equipment, possibly higher capital cost. Others suggest the use of structural materials with little induced radioactivity as a more straightforward approach both to inherent safety and simpler waste disposal.[4]

Insofar as a fusion reactor that produces electricity reliably appears to be more difficult than one whose purpose is merely to manufacture fissile material from fertile material (the fusion breeder), some in the world's fusion community would shift the project's focus away from power production based on D-D or D-T to breeding fissile material. The energy system based on fusion breeders might consist of converter fission reactor "calves" fed by fusion breeder "cows" gathered in closely guarded centers. Most of the energy in such a system would come from the fission reactor calves; all the fissile material, and its reprocessing, would be confined to the few sites at which the fusion cows are located. One fusion breeder might provide enough fissile material to feed a dozen calves. This is in contrast to the fission breeder, in which one breeder could support only one ordinary converter.

The energy systems based on fusion-breeder and fission "calves," and the system based on fission breeder and fission calves are conceptually very similar. Thus in redefining this lesser goal for fusion, one can no longer claim

that the resulting energy system is less radioactive than is the system based on fission, since the fusion breeder itself as well as the light water reactor calves produce hardly less radioactivity than does the original fission system. And the fusion breeder handles large amounts of plutonium or uranium-233; to immunize such a system from the danger of proliferation would require careful control of the fuel cycle, just as in the pure fission system.

All that I have said about fusion so far assumes that controlled fusion, in some version, is scientifically feasible, and that it will prove to be both practical and economical. Though scientific feasibility is now often regarded as being on the verge of demonstration, I continue to be agnostic until the Lawson criterion has been exceeded in a fully realistic plasma; nevertheless, I am almost ready to believe that scientific break-even will be demonstrated in at least one of the new large tokamaks, and possibly in other configurations, within a decade. This would represent an extraordinary scientific triumph, one for which the world's National Laboratories would be justly proud. On the other hand, from scientific feasibility to economic practicality is still an enormous jump. Insofar as the focus might shift to the fusion breeder, rather than the power producer, the competition is uranium from sea water or from low grade ores at, say, $1,000 per kg; or the fission breeder. A gram of uranium-235 from $1,000 per kg natural uranium would cost about $200 per gram. Whether a gram of plutonium from a fusion breeder will meet this cost remains pretty much unknown; and whether the fusion breeder/light water reactor energy system is, all in all, better than the fission breeder/light water reactor system, we do not know.

In the past year the world has spent about $1 billion on the quest for controlled fusion; it has spent about twice as much on the fission breeder. Since the social purpose of these two projects is pretty much the same, one might argue that the amount spent on them should be comparable—<u>if they showed equal promise of achieving their goals</u>. Do fission breeders and fusion show equal promise of achieving their goals? This question has, as far as I know, never been asked seriously, at least not in a way that has affected any allocation of resources. At the risk of offending my many colleagues in the controlled fusion community, I would claim that fission breeders and fusion are in different universes as far as their promise is concerned: breeders have been built and they work; we still do not know whether fusion, even the fusion breeder, will work.

Project Sherwood has most of the characteristics that make it an ideal vehicle for redeployment of the National Laboratories. Its social purpose, inexhaustible energy, is impeccable. It requires large, expensive hardware, and so can be pursued effectively only in the style of Big Science. It remains an extraordinarily interesting and challenging scientific frontier. And because it is so far from commercialization, private support is largely out of the question: Sherwood will be supported by the public or not at all.

These four traits characterized nuclear fission in the earliest days when the National Laboratories were established. No wonder that controlled fusion has fitted so beautifully in the laboratories that developed fission--such as Oak Ridge and Los Alamos. Indeed, fusion is now the largest single project at the Oak Ridge National Laboratory. Moreover, as long as scientific feasibility has not been achieved, or, once it has been achieved, as long as economic practicality remains unproven, the fusion laboratories will not have worked themselves out of a job.

But, the longer it takes to achieve these goals, the more fragile will be the public's support of controlled fusion research. Thus the fusion laboratories face a dilemma: they will lose public support if success is too long in coming, and they will face heavy commercial competition if they achieve success.

Of the two, I suppose the loss of public support, rather than the possibility of commercial competition is by far the bigger problem. From this point of view, I would applaud the strategy advocated by some to focus on the fusion breeder, because the latter is easier to achieve than is the power producer. But in so doing, fusion comes into direct competition with the fission breeder. No longer can fusion claim superiority over fission because it is less radioactive, less prone to proliferation, less subject to accident. The fusion breeder is just that--a source of fissile material, albeit a more sophisticated source than is the fission breeder. And the energy system based on the fusion breeder is itself based primarily on fission.

The fusion community in the United States has not adopted the fusion breeder as its goal: this is still regarded as an incidental step to the achievement of the pure fusion power producer. Nevertheless, I would regard as fairly likely the eventual adoption of the lesser goal, the fusion breeder, simply because the public will tire of supporting the larger goal. Would the

public become weary of the quest even for the fusion breeder? I believe this will depend on the strength of our commitment to the inexhaustible energy system based on uranium and thorium--can this commitment be restored to the pre-eminent position in our social agenda that it enjoyed until the ascendency of the energy revolutionaries? In my earlier analysis, I concluded that breeders, whether fission or fusion, will not be needed until, say, 50 or more years. I argued for continued support of fission breeders because, as these technologies go, 50 years is not a long time. How much truer this is for fusion technology! Forty years have passed since Jim Tuck, Enrico Fermi, and Edward Teller at Los Alamos first raised the possibility of controlled fusion; we still have not exceeded the Lawson criterion in a practical plasma. Thus it seems to me that a rational resolution of the crisis of support that even the fusion breeder will face during the coming decade will require that a fission-based inexhaustible energy system be accepted as an important social goal--one that merits, say, the same kind of social commitment as does space exploration or even such expensive basic science as high energy physics.

Perhaps I am overly skeptical as to the strength of the commitment, at least in the United States, to the goal of inexhaustible energy based on uranium and thorium. But can one blame me for skepticism in the wake of the decision to cancel the Clinch River Breeder? Many of us saw this as a victory for those who find nuclear energy abhorrent: their target was not the Clinch Breeder, it was breeders in general, and therefore, ultimately, an energy system based on fission. The target of these opponents of fission surely encompasses the fusion breeder, no less than the fission breeder; that the fusion breeder has escaped their political attack I attribute to the rudimentary state of its technology. When, and if, fusion research reaches a point where a demonstration fusion breeder can be built, such a device will face the same sort of obstacles that finally killed Clinch River--unless the commitment to inexhaustible energy based upon fission is strong enough to withstand the political attacks from those who would find their personal fulfillment in the abolition of fission energy.

The other strategy, which I believe is more generally accepted by the fusion community, is to develop really clean fusion energy--based on pure fusion reactors that use radioactivity-free structural materials. Fusion power plants based on such materials would be immune from Dr. Logan's partial

melt-down; and they would simplify waste handling. Still, a 1000 MWe fusion reactor contains about 100 million curies of radioactive tritium; this cannot be avoided. Although this is far less than the 15 billion curies of radioactivity in the fission products of a 1000 MWe fission reactor, it is not negligible. I fear that, were the development of "clean" fusion power to succeed, opponents of nuclear power would still find reason to attack the development on the grounds that it is not clean enough.

Redeployment II: Solar Energy and Conservation

In 1973, as the first oil shock hit the world, Dixy Lee Ray, the chairman of the Atomic Energy Commission, was asked by President Nixon to prepare a plan for energy research and development aimed at achieving energy independence by 1980. The resulting document, The Nation's Energy Future,[5] set forth a wide-ranging menu of research on every energy source, and on conservation. The total budget for this expanded research program was 10 billions of 1973 dollars. Much of this was to be spent by the Atomic Energy Commission; in effect, a first step was thereby taken toward converting the Atomic Energy Commission into a Department of Energy with cognizance over all energy sources, not just nuclear energy.

In response to the initiative, the National Laboratories undertook research on solar energy, conservation, and energy storage. Many ingenious devices and insights have resulted: for example, the double focusing parabolic solar collectors, spun-off from high energy physics research at Argonne National Laboratory; the solar power tower designed and built by the Sandia Laboratory; ideas for more efficient and cheaper batteries; and, perhaps most significant, energy-economic modeling. The whole field of energy-economic modeling was in part born, and certainly was strongly nurtured, at the National Laboratories, equipped as they were with very large computers.

But the energy revolutionaries--those who argued that our energy problems could be resolved once and for all by conservation supplemented by solar energy--were not content with this redeployment. Even before their views acquired broad political acceptance in the Carter Administration, the political winds were blowing toward solar energy and conservation. I recall how, in 1974 when I was the director of the White House-based Office of Energy

Research and Development, we proposed the establishment of a separate Solar Energy Research Institute: a national laboratory devoted entirely to solar energy. Such an institute would be manned by people whose futures were tied to solar energy, and who would bring to the development of solar energy the enthusiasm and dedication that could hardly be expected of retreaded nuclear scientists at the existing national laboratories. The Solar Energy Research Institute was eventually established in Golden, Colorado. Though it enjoyed full support during the Carter Administration, it has been cut back by the Reagan Administration.

In Europe and in Japan, many of the original atomic energy laboratories have become, more or less, general energy laboratories, with major attention focused on solar energy in all of its manifestations--wind, photovoltaics, power towers, solar ponds, ocean thermal energy conversion, biomass--and, perhaps most important, conservation. And in several countries, the original atomic energy commissions have had their mandates broadened to cover all of energy.

How successful has this great redeployment been? By far the greatest success has been in conservation. The energy/GNP ratio in the United States fell by about 20 percent between 1950 and 1980. But it would be very difficult to attribute much, if any, of this improvement to any research or policy analysis that has come out of the national laboratories. During this period the price of energy has increased some 1.6-fold in constant dollars: what we see is largely a market response to increased price; it has little to do with research per se. Since the price of electricity has not risen nearly as fast as has the price of oil and gas, electricity has doubled its market share. This too may have contributed to the economy's higher energy efficiency since, as C. Burwell argues, electricity per se conserves primary energy, particularly in industrial processes.

As for solar energy, the results so far have been disappointing. To be sure, windmills have been built; wood is being burned; electricity has been generated in an experimental OTEC system and in a solar pond; a solar power tower operates near Albuquerque. But except where wood is cheap, the energy obtained from the sun is not cheap. The hundreds of windmills deployed in the Altamount Pass in California cannot be economically justified: they have been built largely as tax write-offs by wealthy speculators.

Though progress is being made in photovoltaic technology, a kilowatt hour from an unsubsidized photovoltaic installation in the United States costs more than 50¢. This is five or more times the price of electricity from new coal or nuclear plants. Thus photovoltaics have a very long way to go before one can count on them for a major part of our energy. Because electricity from them is intermittent, photovoltaics, along with many other solar energy sources, cannot provide reliable energy unless they are backed up--either by a grid energized by non-solar sources (or by many stochastic sources, such as widely dispersed windmills, some of which can always be counted upon); or by an affordable storage system. Indeed, the affordable storage system is both the Achilles heel and the Holy Grail of solar electricity: it is all but necessary, yet, so far all the proposed systems are too expensive.

I hope my generally negative assessment of solar energy is not discounted as sour grapes from an old nuclear enthusiast. Despite my impression that the redeployment into solar energy has not yielded very much, I remain convinced that a vigorous research effort, probably focused upon photovoltaics and upon storage systems, makes sense. In the broadest sense, I cannot argue as I have for a commitment to inexhaustible electricity based upon fission and fusion, without extending this commitment to solar electricity--which is also inexhaustible. Solar photovoltaics, after all, now produce electricity--which is more than can be said for fusion. That the electricity costs too much for general use is unfortunate--but certainly we ought not give up on reducing the cost. Moreover, the same arguments about longevity and cost that I invoked for the breeder system hold for solar voltaics: if photovoltaics last longer than their amortization time, electricity from them would eventually be all but costless! In short, the appropriate time scale for photovoltaics development is really much longer than has been generally recognized--and this, perhaps more than any other consideration, justifies their continued investigation in long-lived, governmental laboratories.

In a way, solar energy lends itself less naturally to investigation in large Big Science institutions than do either fission or fusion. Most of the solar devices are too small, and research on them is by and large small-scale, not large-scale. Perhaps, therefore, the main justification for conducting such research in governmental laboratories is its long range. Progress is likely to be very slow--too slow to merit much support from strictly

commercially-motivated entities. If solar energy is ultimately to become a truly large energy source, its development will require patience--more, I would judge, than can be afforded by market-driven industry. The redeployment into solar energy by the National Laboratories, and the establishment of the Solar Energy Research Institute, I regard as well justified.

Redeployment III: National Environmental Laboratories

Environmentalism as a major political force emerged in the United States in the early 1960s with Rachel Carson's Silent Spring. The National Environmental Protection Act was passed in 1969, and acts to protect the air and the water were passed soon afterward.

Even before all this legislative recognition of the environment, the National Laboratories had, since their inception, been obliged to study radioactivity in the environment. The Oak Ridge National Laboratory, for example, had one of the world's largest teams of ecologists, all engaged in studying the fate of radionuclides in the natural environment. All the laboratories were heavily engaged in the study of the effects of radiation on living things. Thus when environmentalism became a powerful political force, many of the national laboratories were well prepared to move into this area. Professor David Rose, while on leave at the Oak Ridge National Laboratory in 1971, went so far as to suggest the partial conversion of some of the laboratories into National Environmental Laboratories, which could examine both social and technical aspects of the environment. The idea was considered briefly by Senator Muskie, who had been responsible for U.S. environmental legislation: but the idea of converting the Atomic Energy Laboratories into Environmental Laboratories was too much for the Joint Committee on Atomic Energy to accept, and Professor Rose's original proposal was never adopted. Nevertheless, large laboratories devoted to certain aspects of environment now exist--the largest is the National Institute of Environmental Health Sciences, which is devoted to epidemiological and biological studies of the effects of the environment on health.

The National Nuclear Energy Laboratories, having primary responsibility for developing energy sources, can mount very broad approaches to the study of the environment: they can examine not only the environmental effects of

effluents from energy systems, but also, because they are intimately involved in the engineering of the devices whose effluents cause the problem, they can offer remedies for reducing the effluents. They are unique in this capacity to examine every aspect of the environmental problem.

One of the most important effluents is carbon dioxide; since 1975, the National Laboratories have been studying the CO_2 greenhouse effect. These studies range from estimates of the future atmospheric burden of carbon dioxide, to modeling of the effect of CO_2 on the global climate, to estimates of the effects of the resulting temperature rise on the environment. Of course, the laboratories' involvement with nuclear energy places them athwart a potent technical fix for carbon dioxide. I refer to a shift to nuclear power as a way of avoiding accumulation of CO_2. France, because of its massive commitment to nuclear energy, will throw less CO_2 into the atmosphere in 1990 than it did in 1980. If the ten countries that are now the world's largest users of energy could make the same shift to nuclear, the carbon dioxide problem would be pushed at least 50 more years forward. Insofar as the National Laboratories, by helping to solve the remaining problems of nuclear energy, can make this shift to nuclear energy more likely, they would be resolving the CO_2 environmental issue in an indirect, but powerful manner.

Altogether, I would judge the shift of the National Nuclear Laboratories into environmental studies to be among their most appropriate redeployments. The environment has no final resolution: there can hardly be a question of working oneself out of a job. No matter how clean the environment, one can always seek a cleaner environment. Nor is it likely that environmental research will be dominated by nongovernmental entities. To be sure, as governmental regulations become stricter, potential polluters will find it to their economic advantage to reduce their effluents; this has happened in the electric power industry, where the Electric Power Research Institute has launched a large research program on acid rain. But the environment is too public, and arouses too many political anxieties, for the government ever to shirk responsibility for the environment. In short, though David Rose's National Environmental Laboratories of 15 years ago were stillborn, they have been resurrected--not as full-blown, free-standing entities, but as important components of the original National Nuclear Energy Laboratories.

Redeployment IV: National Socio-Technological Institutes

Almost 20 years have passed since I suggested converting the National Laboratories into National Socio-Technological Institutes.[6] The argument for such a conversion was based on the observation that the society's concerns are never simply technological: there are always social components of any technical issue. Whether the concern is energy, or environment, or arms control, technology by itself is not enough. Insights and perspectives drawn from scholarly investigation in the social sciences ought to illuminate the issues. Thus originated the idea of National Socio-Technological Institutes: technologically oriented National Laboratories conjoined with think tanks. The think tanks would provide the social perspective; these social perspectives would help in the choice of new technological initiatives, and would help avoid the social dislocation that so often accompanies the introduction of new technologies.

The National Laboratories have, to a degree, become Socio-Technological Institutes, largely as a result of the energy shocks of 1973. The energy shock has brought economics to the National Laboratories: Oak Ridge, for example, now has some 20 economists. Once the ice was broken, other social scientists found congenial homes there. The environmental question has brought in geographers and ecologists. Political scientists, even anthropologists, can be found at Oak Ridge and at other National Laboratories, brought in because technology alone can hardly explain why people reject nuclear energy, or why they have elevated concern over low-level insults to the environment to such prominence.

Our whole Western society has become sensitive, perhaps overly sensitive, to the deleterious side effects of new technologies. This has led, in the United States, to the establishment of the Office of Technology Assessment, and, indeed to the Technology Assessment movement: a program aimed at identifying and forestalling unpleasant social consequences of the new technologies. The conversion of the National Laboratories into National Socio-Technological Institutes can be regarded as a manifestation of this movement.

Whether the social sciences per se are able to do what somewhat naive engineers and applied scientists expect of them--namely, to estimate the social impact of new technologies and to devise policies that might ameliorate

the growing tensions between technology and the public—this is very difficult to say. Technologists may be unaware that even within the social science community important figures such as Professor Lindblom have voiced doubts as to the proficiency of the social sciences in offering solutions for social problems.[7] Nevertheless, my experience with social scientists who are involved with technology assessment and risk analysis at the National Laboratories, convinces me that their perspectives and insights are useful, even though their prescriptions do not have the reliability of those of an expert in stress analysis, nor a theoretical sanction as solid as classical thermodynamics! But technologists ought not castigate social scientists: the problems they deal with are vastly more complicated than those dealt with in stress analysis or thermodynamics. Despite the limitations of the social sciences, one cannot doubt that their presence has given to the laboratories' technological ventures much more social sophistication and political sensitivity than was the case even a decade ago.

New Issues

I have identified four different problems around which the National Laboratories have remobilized: fusion, solar energy and conservation, the environment, and social implications of new technologies. I have also insisted that the original purposes of the National Laboratories—nuclear power that is fully acceptable in the short run and inexhaustible in the long run--have not yet been achieved. Until these goals have been achieved, the National Laboratories' original purpose remains valid. But reality is never so tidy: one does not suddenly reach an objective, and redeploy all at once--redeployment occurs over many years. The budget for fusion has grown to its present size over more than 30 years. We ought, therefore, to be thinking even now about new big problems that can occupy the National Laboratories when the vogue and support for the existing ones wanes. I shall suggest a few that seem important to me, though I make no claim that mine is an exhaustive list.

The growing role of Basic Research. When the National Laboratories were first formed during World War II, we drew no distinction between our applied research and basic research. Everything about the nuclear chain reaction was new: we would work on methods for solving Boltzmann's transport equation one

day, and then would apply our results the next day to the design of the Hanford plutonium-producting reactors. But as the science underlying the chain reaction was worked out, the basic science at the laboratories has diverged more and more from the applied work; and basic sciences grew relative to the latter as the applied work moved to the industrial laboratories.

This growing trend toward basic research at the National Laboratories was noted as long ago as 1965 by Dr. Arthur Vick, former Director of Harwell.[8] In a way it makes good sense, since basic research is open-ended and therefore fits well in a long-lived, government laboratory. On the other hand, the universities have traditionally been the home of basic research: as the National Laboratories have moved into basic research, they have run into competition with the universities--and this competition can never be entirely resolved.

One must distinguish between basic research that is part of Little Science--small groups of investigators working with small equipment; and basic research that is part of Big Science. On the whole, the competition I have mentioned is most severe where the National Laboratories conduct Little Science, which university researchers regard as their own province. Scientists at the National Laboratories generally are shielded from the peer review process that university scientists are subjected to, and this is regarded as being unfair by the universities. The National Laboratories, in justifying their conduct of Little Science outside the peer review system, argue that much of their basic research is relevant to the pursuit of underlying applied missions; that the individuals conducting basic research are available for help on applied jobs; and that, anyhow, the informal reviews of their basic research is at least as effective as is peer review in weeding out nonsense.

The role of the National Laboratories in Big Science is, of course, much less controversial. From their inception the laboratories afforded facilities that were unique--either because they were too expensive or too dangerous to be provided at the university. One need only mention the Zero Gradient Synchrotron (ZGS) at Argonne, the High Flux Isotope Reactor (HFIR) at Oak Ridge, or the Los Alamos Meson Production Facility (LAMPF) as examples. Here there is no question as to the appropriateness of such activities, nor is there any question as to their success. On the other hand, each of the laboratories faces a hard choice whenever a facility of this magnitude, which sometimes may dominate the entire laboratory, becomes obsolete. Or, when a new

instrument of Big Science is proposed, should it be built at an existing National Laboratory or at a new laboratory devoted specifically to this purpose? This issue arose at the time the Fermi Laboratory was built in Batavia, Illinois, just 50 kilometers from the Argonne Laboratory. The latter had already established itself as a successful high energy laboratory with its Zero Gradient Synchrotron; yet, the Atomic Energy Commission chose to create a new laboratory nearby. Judged by the success of the Fermi Laboratory, one cannot fault this decision, even though the Fermi Laboratory was more expensive than would have been an extension of Argonne to accommodate the huge new accelerator.

Altogether I would judge that the National Laboratories' role as facility centers wil continue to be a valid and appropriate role for them. LAMPF, HFIR, ZGS--all of these have been extremely successful; and as energies and intensities go up, one would expect that other such instruments will be built and used at the National Laboratories.

Applications of Nuclear Energy. Nuclear reactors produce electricity; yet electricity accounts for only 35 percent of the world's primary energy. Can nuclear energy be used for other purposes, in particular large-scale industrial processes and, even more important, automotive transport? Such a transition away from fossil fuel, if successful, might lead to a world no longer beset by a spectre of accumulating CO_2, or even acid rain. But the obstacles, of course, are enormous.

One of the first such ideas was R. P. Hammond's proposal in the 1960s for desalting the sea with heat from very large nuclear reactors. As we look at the economics today, the ideas seem naive--nuclear power is too expensive today to be used to desalt sea water. Suppose, however, the Bolsa Island project of 1968, instead of being cancelled, had been built. The project called for two 650 megawatt pressurized water reactors to provide electricity and 150 million gallons of water per day to the City of Los Angeles. Had the project gone ahead on its original schedule, it would have been completed before the cost of nuclear power had risen out of sight. Ten years later, the project would have looked very much better. And twenty years later--say, by 1995--Los Angeles would be grateful for the courage and foresight of the Metropolitan Water District for going ahead with the project.

Other schemes in this same genre are Professor Schulten's Adam and Eva[9]--a system that uses high temperature heat from nuclear reactors to convert methane and water into hydrogen and carbon monoxide which could then be shipped through pipes to process industries; or the many, so far unsuccessful, attempts to split water into hydrogen and oxygen with nuclear heat;[10] or even W. Haefele's scheme for devising an energy regime based on the conversion of fossil fuel to methanol,[11] and the all but complete sequestering or recycle of combustion products.

Whether bypassing of electricity is the key to wider use of nuclear power, or whether, as Burwell argues, the trend toward electrification we now are seeing will continue because traditional non-electric process industries are switching to electricity, remains to be seen. But generally, one must have sympathy for these attempts to visualize a more rational energy system, one that emits neither CO_2 nor acid rain, and that can be the basis for a long-term environmentally benign industrial society.

Technological Optimism and President Reagan's Dream

I realize that much of this must sound hopelessly, naively optimistic. But I would insist that the current technological pessimism that pervades our intellectual life is at least as overdrawn as was my technological optimism of 20 years ago. This atmosphere of technological pessimism could greatly complicate the future redeployment of the big laboratories. After all, the original mission of the institutions reflected an extraordinary leap of technological faith--that nuclear fission could be converted into something practically useful. Again, President Kennedy's commitment to put a man on the moon reflected a technological optimism of the highest order. The resulting big project matched admirably the character of the large space laboratories. And the largest redeployment of the nuclear fission laboratories, fusion, was based on an even greater technological optimism.

Have we lost this sense of technological optimism, have we given up our taste for large, non-market-motivated technological spectaculars? Are we so disenchanted with what some regard as the failure of fission as to prevent us from addressing new technological spectaculars because we cannot be sure that

they will succeed? Have we run out of ideas for major technological spectaculars that have enough plausibility to command the attention of large governmental laboratories and the support of the government agencies? Will the future of the laboratories lie in competent, indeed brilliant, picking away at small problems, no one of which matches in scale or even significance, such spectaculars as the breeder or fusion?

I do not know the answer to this. Yet, at the risk of antagonizing many of my European, as well as American, readers, I would call attention to a direction that certainly qualifies as a technological spectacular, that addresses the most important of all social issues, that demands unlimited technological optimism, and that may prove an ideal vehicle for redeployment of the weapons laboratories. I have thus far said very little about the nuclear weapons laboratories--Los Alamos, Sandia, Livermore--mainly because I am less familiar with them than I am with the nuclear energy laboratories. Nevertheless, I do not believe I compromise any national secrets by suggesting that further development of nuclear bombs can hardly lead to more than incremental gains. The laboratories, having sensed this, have redeployed into such things as fusion, solar energy, climatology, laser enrichment of isotopes, and monitoring of arms control agreements.

I would suggest that President Reagan's highly controversial Star Wars speech could serve to set the weapons laboratories along new technological paths that might have the most significant of all social purposes--conversion of the current posture of Mutually Assured Destruction to a posture of Mutually Assured Survival. President Reagan, in his March 23, 1983 speech, displayed an extraordinary, some would say foolhardy, technological optimism. He called for the technical community to come up with a leakproof shield against ballistic missiles--a shield so perfect that, as he put it, peace would no longer depend on each side holding hostage 100 million of its opponents' citizens. Technology was being called upon by the President to rescue humankind from the extraordinary predicament into which technology had placed it.

This degree of technological optimism from a president of the United States exceeded by far President Kennedy's call for the moonshot: it exceeded, even, President Roosevelt's call for an atomic bomb. As visualized by the President--an all-but-perfect area defense against ballistic missiles, so

efficient that citizens need no longer fear the spectre of nuclear war--this goal is unattainable. Many, if not most, of the scientists who had been involved in arms research were quick to denounce the President's call as being impossible. More than that, many in the arms control community argued that an area defense, even if it could be achieved, was destabilizing. If the United States deployed such a defense, it need no longer worry about a retaliatory strike from the Soviet Union. Such deployment would, therefore, be viewed by the Soviet Union as prima facie evidence that the U.S. was planning a first "counterforce" strike against Soviet retaliatory weapons; the U.S. defensive system would be adequate to take care of the Soviet's ragged retaliation.

Not all scientists regarded President Reagan's proposal in this light. Perhaps most prominent was Professor Freeman Dyson of the Institute for Advanced Study: in his Weapons and Hope, he called for a transition to a defense-oriented instead of an offense-oriented world.[12] Dyson came to his somewhat unorthodox views as a result of his experience as an operations analyst in the Royal Air Force in World War II. He concluded that defense is morally superior to offense; and though he fought for the British, his sympathies were with the German fighter pilots who tried to thwart the British-American bombing raids on Berlin and Dresden.

Two years after Reagan's call for defense, I believe one is seeing a gradual shift in attitude toward Star Wars. No one seriously believes a defense that can fully neutralize nuclear bombs delivered by cruise or ballistic missiles is possible. Yet many analysts concede that even an imperfect defense could be useful, and that a partial defense of missile silos is feasible. Such a defense would extract a "price" of, say, eight re-entry vehicles for every silo destroyed. Such an imperfect defense in effect diminishes the effectiveness of the opponents' first strike weapons; one therefore need not maintain as many of one's own weapons to maintain de facto parity. In short, deployment of an imperfect defensive system around one's own silos reduces their vulnerability and thus adds to stability.(This was exactly the argument offered for the "race track" basing mode of the MX--to reduce vulnerability.) Moreover, one needs fewer weapons to maintain a balance if the weapons are afforded a degree of protection against incoming ballistic missiles: the defense system can in principle serve as a shield behind which one can dismantle some offensive weapons--that is, exchange one

kind of parity, a mixture of some defensive and some offensive weapons--for a more threatening parity that involves larger deployment of offense alone. Mutually assured destruction still operates, but at a lower force level. Dr. Jack Barkenbus and I have called this strategy "Defense-Protected Build-Down"[13]--i.e., a build-down, negotiated or even unilateral, made politically feasible by the erection of a defensive shield, even an imperfect shield.

Two other points have emerged that blunt some of the opposition to Star Wars. First, and perhaps most important, all war, and particularly nuclear war, is uncertain. Had Admiral Tojo foreseen the ultimate outcome of the attack on Pearl Harbor, or Adolf Hitler the outcome of Barbarossa, would these operations have been launched? Defensive systems add to the uncertainties facing a would-be attacker. As Donald Snow says in his The Nuclear Future,[14] anything that increases the uncertainty of the outcome of a nuclear war will reduce the likelihood of a nuclear war.

The second point is one that has always troubled defense analysts, but has never been resolved. If two parties engage in an offensive confrontation, they achieve parity when both sides have the same number of first strike weapons. If three parties engage in such confrontation, parity is impossible to achieve (unless no party has any weapons) because each party would require as many weapons as the other two combined. This troublesome point was generally regarded as too theoretical to be of much interest. Yet the Intermediate Nuclear Force negotiations foundered on exactly this point, with the Soviet Union asking for as many warheads as the United States, England, and France combined, the United States demanding parity with the Soviet Union alone. This n-party offensive instability disappears if all sides deploy only defensive weapons; and this stability persists in a mixed offensive/defensive posture as long as each party's defense is strong enough to destroy all offensive weapons that might face him.

I apologize for this digression into the Talmudic niceties of arms control theories. Yet, I believe some such arguments are necessary to justify what is perhaps the major redeployment that is now going on in the U.S. laboratories--the development of non-nuclear defenses against ballistic missiles. President Reagan has proposed spending $26 billion on his Strategic Defense Initiative; though this leap of technological faith is regarded by many as wrong-headed, both technically and politically, I cannot agree for the reasons

I have touched upon. I believe Freeman Dyson is fundamentally more correct than are his detractors: we are more likely to rid the world of the curse of nuclear weapons from a position of defense than from a position of offense. The laboratories will be fulfilling a noble, not an ignoble, social purpose if they can devise the technologies that can allow the world to make this transition from offense to defense. Moreover, European and Israeli laboratories may be drawn into this quest: the United States has invited laboratories in these countries to participate in the Strategic Defense Initiative. Perhaps this is a first step in internationalizing ballistic missile system defense, a possibility held out by President Reagan.

Thus far I have spoken only of defense against strategic weapons; what about defense against tactical weapons, or even against conventional armor carrying conventional armaments? This, after all, is the problem faced by Europe: can NATO safely adopt a no-first-use nuclear policy; and can it match the Warsaw Pact's armor by means of clever defensive weapons? I am much influenced in these matters by the views of the former Assistant Secretary of Defense for Research and Development, Dr. William Perry. Speaking at Los Alamos in 1982, Dr. Perry insisted that defensive weaponry had become so effective that it was no longer necessary for the West to match the East tank-for-tank.[15] If this was the situation in 1982, can we not look forward to a future 10, 20, 30 years from now when defensive systems become so overwhelming that neither non-nuclear nor nuclear aggression makes sense? And would not the research institutions responsible for providing the technologies that make this great transition possible be fulfilling the greatest social purpose of all--the elimination of organized armed conflict as a means of resolving political disputes? I realize that all this must sound impossibly idealistic, perhaps having little to do with the real world. But President Reagan's March 23, 1983 speech was part of the real world, however much it annoyed arms control intellectuals. The President displayed a technological optimism whose absence I have repeatedly decried. This optimism, though overblown, I found refreshing; and, as the years go by, we will learn whether the optimism is misplaced or will lead to the safer world all of us, especially President Reagan, seek.

Technological Pessimism and Basic Science

I have spoken almost entirely of the challenges that face the Nuclear Energy Laboratories as their original mission disappears, and they scramble for survival in the face of a widespread technological pessimism. But, as I said earlier when I quoted John Wheeler, the connection between fission and the most arcane parts of Big Science--High Energy Physics or even Heavy Ion Nuclear Physics--though conceptually weak, remains strong in the common organizational sources of support for both nuclear energy research and high energy physics, and possibly in the public's perception of a linkage. Is it possible that continued disenchantment with nuclear power, coupled with the growth of the Green anti-technological movement, whose primary target is our modern technological society--that this technological pessimism wil spill over to a disenchantment, and therefore loss of support, for basic big sciences that are, rightly or wrongly, regarded as having nuclear connections?

So far these sciences seem to have escaped unscathed, at least in the United States. And, I suppose the possible military application of ion beams could serve as a basis for support of accelerator development, even of accelerators having little to do directly with military hardware. Moreover, in the United States, basic sciences generally and High Energy Physics particularly, have fared well under the Reagan Administration. But the costs of these sciences continues to rise. The Super-Conducting Super-Collider is estimated to cost several billions of dollars; can an expenditure of this magnitude survive future political buffeting without a clear and continuing popular mandate for such inquiry?

One certainly cannot say. I should think, however, that a political climate supportive of such arcane, yet extremely expensive, investigation is more likely to flourish where science per se is seen as man's servant, not as man's master; where technology is perceived as being good, not bad; where technological optimism, not technological pessimism, holds sway. In short, the success of the great technological adventures of this century--most notably nuclear power--is not unrelated to the future success of Big Science itself, even those parts of Big Science that have traveled far from their roots in fission. One hopes that the current fashion of technological

rejection will prove to be a passing phase, to be replaced by a renewed faith in our big technologies, which are based on continuing achievements of the establishments of Big Science.
